Rip Van Winkles

REMEMBER Washington Irving's lovable, irresponsible Rip Van Winkle? How persistently he tricked himself! Time and again when temptation was too strong and nature too weak, he would lift his glass and say, "I won't count this one".

THERE are many Rip Van Winkles in the world right now—some are weak in self-control; some are sadly behind the times in a matter of vital importance to them. They are the unfortunates among the million diabetics in the United States today.

Old Rip's giant spree put him to sleep for twenty years—but "food sprees" are bringing death to present-day Rip Van Winkles because they lack self-control or lack knowledge as to what insulin can do for them.

Thanks to insulin, a diabetic is not confined nowadays to a scanty, spirit-breaking diet. He can have varied and much more appetizing food than was allowed in the old days. But even now, if he fails to find out what he should eat and drink—or if he fails to be steadfast in obeying orders—he practically commits suicide.

When diabetes attacks, it has come to stay. It rarely gives up. A diabetic has one of two choices, either to put up a cheerful, continuous fight or weakly surrender. Half-way defense spells defeat. But a courageous, unyielding fight is almost sure to win.

One great danger is that with the aid of insulin and correct diet, the diabetic feels so much better that he is lulled into a false sense of security. He takes liberties with his diet or neglects to take the insulin as directed. Then, with crushing swiftness, diabetes may claim another victim.

© 1929 Metropolitan Life Insurance Co.

Thousands of diabetics are not even aware of the fact that they are in danger because they have not had a physical examination which would have revealed the presence of this old enemy of mankind and because, also, during most of its course, diabetes is painless.

Of the 20,000 deaths caused by diabetes last year in the United States, 8,000 were of the acute type ending in coma. Yet a world-famous specialist says, "Diabetic coma is always preventable and nearly always curable... Many of my patients have actually lived longer than would have been expected of them had they been normal, healthy people".

* * * *

The deathrate from diabetes is rising. It can be forced downward. The Metropolitan's booklet, "Diabetes," together with recently published information for physicians and their patients on prevention of diabetic coma, will be mailed free on request. Ask for Booklet 1A0.

A Reduction in Long Distance Telephone Rates

*An Advertisement of the
American Telephone and Telegraph Company*

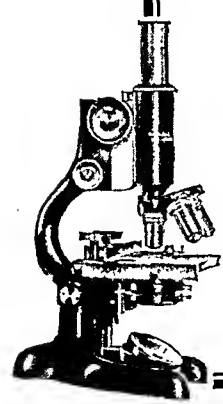

ON JANUARY 1, 1930, there is effective a reduction in various long distance telephone rates in the Bell System which on the present volume of calls means a saving of more than \$5,000,000 a year to the telephone-using public in the United States. This is the fourth reduction in long distance rates within a little more than three years. On October 1, 1926, they were reduced by \$3,000,000. On December 1, 1927, a reduction of \$1,500,000 went into effect. On February 1, 1929, there was a reduction of \$5,000,000.

THESE REDUCTIONS are in accordance with the aim of the Bell System to continue to furnish the best possible telephone service at the least cost to the public. Earnings must, of course, be sufficient to permit the best possible telephone service at all times and to provide a reasonable payment to stockholders with an adequate margin to insure financial safety. Earnings in excess of these requirements will either be spent for the enlargement and improvement of the service, or the rates for the service will be reduced. This is fundamental in the policy of the management.

The Centrifuge for MILK TESTING

Fulfills the speed requirements of the Babcock test. Stands up under daily use.

This centrifuge was designed for and is used by Milk Inspection Laboratories.

The base is a rigid casting; the parts are accurately machined and balanced and can be completely lubricated by easily accessible cups. A rheostat is provided to control the speeds.

The International Centrifuge will swing the standard 6-inch bottle; is 19 inches high without stand; aluminum bronze outside, white enamel inside.

Centrifuge with 8-bottle head and trunnion cups, and speed rheostat, without stand. Price, \$129.80

(Specify voltage and current.)

The Centrifuge Stand absorbs the vibrations, is easily moved, brings centrifuge to convenient height, and supports rheostat.

Price, \$38.50

For all field tests and where
time is an important factor...

THE FROST LITTLE PLATE METHOD FOR COUNTING BACTERIA IN MILK

Wherever time saving is important the Frost Little Plate method is recognized by bacteriologists as the fastest simple way of making an accurate count of the bacteria in milk.

Thus, while the entire apparatus for the method is built for the utmost convenience in conducting field tests, many important laboratories use the same apparatus and method as standard routine technique.

The constantly growing demand for this equipment since the publication of the method in 1921 is due to the fact that, while reducing the total time required for the test to, at the most, a third of that necessary in the older plate methods, there is no loss of accuracy and no need for more specialized technique than is called for by previous standard counting practices.

There is also in the Frost method the additional advantage of economy occasioned by the substitution of microscope slides for Petri dishes and by the much smaller quantity of medium used.

For complete information on this equipment and a detailed discussion of the method ask for our free Bulletin 97-G.

Leadership

in RESEARCH ~ ENGINEERING
MANUFACTURE ~ DISTRIBUTION

CONCEIVED in the spirit of service to the Dairy Industry, Cherry-Burrell points with a certain pride to promises fulfilled.

Large scale manufacture by modern practice, governed by precision methods, has already effected improvements in quality—and our production engineers pledge still greater achievements.

A Department of Research is achieving leadership in the field of scientific investigation and practical solution of the varied problems confronting the Dairy Industry as well as in the field of engineering, design and manufacture.

Departments of Engineering and Design, captained by some of the most eminent engineers in the industry have effected vital improvements—have brought out a number of completely new designs—and will continue to keep Cherry-Burrell equipment in constant pace with the industry's development.

Distribution and Service have been made national, yes international, in its scope so that already it is said that Cherry-Burrell Service is as close as one's telephone.

DISEASE *and* THE MAN

By GEORGE DRAPER, M.D.

Associate Professor of Clinical Medicine, Columbia University

In this volume the author develops that Hippocratic trend of modern medicine which requires one to study not only the *disease* but the *man*, and to study the man himself from every angle of his personality.

The author thus considers man in four aspects—morphological, physiological, immunological, and psychological. From the intensive experiments carried out by himself and his associates at the Constitution Clinic of the Presbyterian Hospital in New York, it has been found that patients suffering with the same disease displayed strikingly similar characteristics in the four categories above mentioned. "In many instances," says the author, "these likenesses have recurred with such uniformity that their presence has materially aided in diagnosis."

Does Your City Buy Enough Health?

Does your city pay enough to get a competent man to accept the vitally important post of full-time Health Officer? Is your Health Department on duty all day and every day? Can you protect your own health and that of your family in a city which buys only part-time health-protection for its citizens?

HEALTH records show that cities which have able Health Departments and able Health Officers, and that counties with adequate health units, have lowered their deathrates and saved millions of dollars in reducing costs attendant upon unnecessary illness.

Does your own city employ the available scientific methods of preventing the spread of communicable diseases?

Does it inspect and protect milk, regulate health conditions in schools and factories? Does it support health centers which demonstrate educational

A digest of an Annual Report of the Board of Health in a city of 31,000 inhabitants which has an enviable health record will be sent to you without charge. With the report

measures for disease prevention and personal hygiene?

If you live in a city which does not have the full benefit of all modern precautions, you can do a great service by finding out all that should be done and bringing such influence to bear as is necessary to make health conditions in your city what they ought to be.

Your Board of Health and your Health Commissioner may need additional ordinances and appropriations in order to expand their work. Remember—they cannot work without tools! Back them up.

also will be sent a complete set of the Health Ordinances which should be in force in every properly governed city. Address Booklet Department 2A0.

Want to Get Ahead?

The great English writer, Arnold Bennett, said, "I suppose that for the majority of men the suspension of income for a single month would mean either bankruptcy, the usurer, or acute inconvenience".

A MAN has small chance to get somewhere and be somebody if he is entirely dependent upon his next pay-check. He is likely to be as helpless as a child if his income stops.

Many a man finds himself in a rebellious frame of mind and sorry for himself because he is "broke". He feels bottled-up, half stifled, almost shackled and handcuffed. Unhappy in his work, he does it half-heartedly, badly.

He wants to quit his job but he doesn't dare. His boss would like to discharge him but waits because he is sorry for him and his family.

If a man has not learned how to live within his income, it makes little difference whether he earns \$1,000 or \$10,000—he will always be in trouble. But budgeting his weekly or monthly salary to cover expenses for the necessities and comforts of life will show him how to live within his income whatever it may be.

Do you know how the experts arrange a budget for salaries from \$1,000 to \$10,000? Do you know what per cent of the income should be spent for each of the general expense items—food, shelter, clothing, household operating expense, insurance, education, entertainment and investment?

When speculation is substituted for in-

vestment the last hope for safety usually vanishes.

Budgets have solved money problems in many homes. A typical illustration is furnished by a woman who provided a good home for husband, high school daughter and 12-year-old son on \$200 a month. She reported that when they attempted to live without a budget they were always in debt and worst of all in mental and physical distress. Since their conversion to "the budget way" they have found they are able to live better and save 10%.

Have you ever experienced the peace of mind and satisfaction that result from an intelligent budgeting of your income? With necessities provided for and a little money left over you have a far better chance to get ahead.

Send for booklet entitled, "Let Budget Help", which was written with a full understanding of the problems of those with limited incomes. Use coupon above.

THE WESTERN ELECTRIC COMPANY SEARCHES THE WORLD FOR MATERIALS, AND FASHIONS THEM INTO THE EQUIPMENT OF A NATION-WIDE TELEPHONE SYSTEM

That time and distance may be subject to your voice

An Advertisement of the American Telephone and Telegraph Company

THE Bell Telephone System shapes the stuff of the earth to your communication needs. It delves into the forces and methods that enable you to project your voice where you wish. It searches the world for the materials needed to put its discoveries at your command, and fashions them into the connected parts of a nation-wide system.

It has dotted the nation with exchanges, and joined them and the connecting companies with the wires and cables which enable you to talk with anyone, anywhere.

Each of the 24 operating companies of the Bell System is attuned to the needs of its area. Each is local to the people it serves and backed by national

resources in research, methods and manufacture. Each has the services of the staff of the American Telephone and Telegraph Company, which is continually developing improvements in telephone operation. Each has the advantage of the specialized production of the Western Electric Company. This production embodies the results achieved by the scientific staff of the Bell Telephone Laboratories, one of the great industrial research institutions of the world.

Your telephone company is in a position to offer you the service which you have today because the Bell System is organized to meet your growing communication needs with increasing satisfaction and economy.

DARE'S HAEMOGLOBINOMETER

Electrically Operated

This instrument does away with the use of small bore pipettes which are hard to clean, and the blood is used undiluted—thus eliminating error.

The color scale is a wedge of glass, which is more permanent than solutions.

It is made in two types—one for operation by attaching to the ordinary lamp socket, and one for illumination by battery supplied in the handle, and which can be renewed. The latter form is very convenient for use at the bedside in cases where the electricity is not obtainable.

The pipettes consist of two pieces of flat glass so arranged in a holder that there is a standard space between, giving a standard amount of blood, and allowing the two glass plates to be removed for cleaning.

Price of either type.....\$39.00

Further particulars upon application.

(4014)

"SILENCE"

A KAHN TEST SHAKER AND THE
NEW SILENCER

The Fisher Silencer was designed to eliminate the unavoidable noise caused by the Kahn Shaking Machine.

It muffles the clatter of the oscillating tubes, it also shields them from dust and dirt.

The Celotex lined box is ruggedly constructed and makes the machine easily portable.

Fisher Silencer—\$18.00

Fisher Shaking Machine

FOR THE KAHN TEST

To insure the correct shaking rate this machine is directly connected to the motor.

It is designed to take care of the needs of large and small laboratories and works equally well with one or six racks.

Price, for 110 volts, A.C. (without racks)
\$70.00

INTERNATIONAL HYGIENE CONGRESSES

Dresden, Germany, May-October, 1930

DRESDEN has been selected as the center for the joint meeting of over 200 scientific associations dedicated to the study of hygiene in all its phases.

This international forum—the greatest in its sphere in three decades—will coincide with the opening of the Deutsche Hygiene-Museum, so eagerly awaited by the scientific world.

The International Hygiene Congresses in Dresden this summer constitute an international post-graduate course in the sweeping advances that have been made in all departments of hygiene since the war. It is conducted under the joint auspices of the German Reich, the Free State of Saxony and the City of Dresden—and represents the official participation of the League of Nations and the governments of twenty countries.

Applications for membership in the American Delegation should be addressed to the

Prevent in time

Long hours of undisturbed sleep at night and periods of rest during the day help to ward off tuberculosis in later years.

© 1930 Metropolitan Life Insurance Co.

THE tuberculosis deathrate has been cut in half in the last twenty years largely by better living conditions among the working population and the successful treatment of active cases. Now medical science has an even more brilliant victory in its grasp—the checking of the disease in children before it develops.

Children who come in frequent contact with anyone who has active tuberculosis are in grave danger, though they may look the picture of health and have none of the familiar warning signs — underweight, a cough, fatigue and poor digestion.

A large number of deaths from tuberculosis occur between the ages of 25 and 45. Yet in most of these cases the disease began in childhood, though there may have been a re-infection at some later time.

Contrary to the old-time belief, heredity does not plant the germs. Close contact with the disease in active form is usually responsible. The disease may lie dormant for many years and then flare up and become active following physical or mental strain, too heavy or too prolonged.

But there is no need to guess whether or not a child who has been exposed has

picked up the germs. Modern science can now discover whether any damage has been caused by them. No longer are doctors compelled to rely merely upon such tests as tapping the chest, listening to the breathing, examining the sputum. They can be reasonably sure of correct diagnoses by including X-ray and tuberculin tests. Results from tuberculin tests are especially significant in children.

All children should be kept away from people who have tuberculosis. They should have regular, thorough physical examinations. If tuberculosis is discovered, modern restorative methods should be applied immediately.

Every child, no matter how healthy or sturdy, needs plenty of sleep, plenty of proper food, plenty of sunshine and fresh air. But the child who has picked up the germs of tuberculosis and is beginning to react to them needs additional care and a scientific health-building program under wise medical direction.

The Metropolitan Life Insurance Company will gladly mail, without charge, its booklet, "The Care and Prevention of Tuberculosis", to anyone who requests it. Ask for Booklet 4A0.

What about taste?

DO you have to apologize for the taste of the medicines you prescribe? Or do your patients still believe innocently that the medicine must be bitter to be efficacious?

Agarol the original mineral oil and agar-agar emulsion with phenolphthalein, is for that up to date generation that wants its medicines in the proverbial "sugar coating."

No excuses are needed for its taste anymore than for its effectiveness. Agarol is exceptionally palatable without artificial flavoring. It flows freely from the bottle, and can be mixed with any liquid or soft food.

Just enough mineral oil to carry unabsorbable moisture to the intestinal contents, keep them soft, and so make evacuation easy and painless. By *gentle stimulation* of peristalsis, Agarol makes the result certain, and aids in reestablishing regular habits.

*One tablespoonful at bedtime
—is the dose*

Final decision on the true worth of Agarol rests with the physician. We will gladly send a twin package, with literature, for trial.

AGAROL *for Constipation*

1855 • SEVENTY-FIFTH ANNIVERSARY • 1930

From this Saneto closet, C10674, equipped with a water-controlled vacuum breaker flush valve, no contaminated water can be siphoned into the water system.

Stemming a possible source of post-operative infection

Post-operative infections occurring singly and in groups have been the object of frequent investigations. Crane Co., collaborating with the Chicago Board of Health, has discovered one of the most pernicious sources of these infections . . . and has stemmed it.

The cause, as was demonstrated at the last convention of the American College of Surgeons, is found in the siphoning of polluted water from fixtures with submerged inlets into the main water system,

This diagram illustrates how polluted water can be distributed by siphonage through the clean water pipes.

where it can be drawn into other fixtures.

The remedy, as perfected by Crane engineers, is a vacuum breaker valve with which baths, sinks, closets, all such in-

fection threatening fixtures can be equipped. It provides absolute assurance against back siphoning.

This valve can be examined at the National Crane Exhibit Rooms. If one of them is not convenient to you, full information can be had by getting in touch with Crane hospital plumbing experts.

EACH CALL MUST BE HANDLED SEPARATELY, EACH FITTED TO THE NEEDS OF THE
INDIVIDUAL WHO MAKES IT

65 million calls a day . . . each one made to order

An Advertisement of the American Telephone and Telegraph Company

WHEN you pick up your telephone, you may use \$10,000 worth of equipment to talk to your neighbor three blocks away, or \$10,000,000 worth of equipment to talk 3000 miles across the continent. Each call must be handled separately, each made to order. To render this service in a way that fits the needs of the American people, the operation of the System is conducted by 24 different companies, each adapted to the area it serves.

These Associated Companies have the benefit of study and analysis by the staff of the American Telephone and Telegraph Company, leading to progressive improvements in service.

Each of the Bell Companies takes advantage of the research findings of the Bell Laboratories, commanding scientific talent unsurpassed in any industry.

The quality and precision manufacture of the telephone equipment and apparatus used by the entire System are assured by the specialized production methods of the Western Electric Company, which manufactures for the Bell System.

Today the Bell System is building ahead of the requirements of the public—to the end that the people of this nation may have the greater telephone facilities which they will need tomorrow.

MUNKTELL'S SWEDISH FILTER PAPER

Munktell's Swedish filter paper has been on the market for many years and it may be said that it has become the standard by which other papers are measured, grade for grade.

J. H. Munktell makes many different types of filter paper, in order to be able to furnish a paper suitable to a large number of uses. These varieties cover the entire field of usefulness between the highest grade of analytical work and the uses calling for less expensive papers for general purposes.

We shall be pleased to correspond with anybody regarding these papers, and to furnish samples and literature giving the ash and other properties of the paper.

COMPLETE STERILIZATION ABSOLUTE CLEANLINESS

The CABINET COOLER

by
CHERRY-BURRELL

IN this new cooler, acclaimed by leading engineers and plant operators as one of Cherry-Burrell's most important contributions to the dairy industry, unusual cooling efficiency goes hand in hand with a degree of sanitation hitherto unequalled.

With side covers closed, the milk flowing through the CABINET COOLER is completely shielded against dust, dirt or any atmospheric impurities.

With side covers opened, the CABINET COOLER is instantly accessible for cleaning—for thorough cleaning in all its parts.

With side covers closed, the CABINET COOLER forms a true sterilizing chest and may be completely sterilized with steam.

We will be glad to give you further details of this truly remarkable advancement in cooling.

Why Risk Typhoid?

20 times more dangerous than lightning!

© 1930 Metropolitan Life Insurance Co.

WHEN lightning flashes and thunder roars, timid folk are often frankly scared and even the most stout-hearted are awed. They can see the threatening danger against which they are helpless. Yet most of these very people ignore an unseen danger against which they can protect themselves. It is typhoid fever, and it costs twenty times more lives than lightning.

Typhoid kills one out of every ten attacked.

Those who recover are left in such a weakened condition that for two or three years following an attack, the deathrate among them is twice the normal rate. Sometimes typhoid leaves after-effects from which the patient never recovers.

Most cases of typhoid are contracted by people away from home—touring, hiking, camping, traveling. The disease is caused by eating or drinking something contaminated by typhoid germs. Water that tastes delicious and looks crystal clear, or raw milk and uncooked foods may carry the disease. If you swallow enough typhoid germs and are not immunized, typhoid fever is almost certain to develop.

But you need never have typhoid fever. It is one of the few preventable diseases.

By means of three simple, painless inoculations—entirely safe and leaving no scar—your doctor can make you immune from typhoid fever for two or more years. The United States Government tests and approves all typhoid vaccine before it reaches physicians.

Before you start on your summer outings in the country, consult your physician as to the advisability of being inoculated. Make sure that typhoid will not claim any member of your family. Metropolitan will mail free its booklet, "The Conquest of Typhoid Fever." Ask for Booklet 6A0.

FAILURES *at living*

MEN OF AFFAIRS, women outstanding in professional careers—"successful people" to everyone else. But you know them to be utter failures, failures at so simple a thing as just living. Bundles of nerves, hypochondriacs, spoiled children—they've violated, carelessly flouted, nearly every rule of sane living.

You can help them if they'll work with you. But often you encounter special difficulty in their abuse of caffein drinks.

You can help many of these

patients by suggesting Postum. It answers that craving for a comforting, hot drink. Postum's rich, full-bodied flavor stimulates the appetite with its hearty goodness. Nothing in Postum to harm and plenty of old-fashioned wholesomeness—deliciously roasted whole wheat and bran, slightly sweetened. In more than two and a half million homes Postum is the favorite mealtime drink. A real aid in cases of under-nourishment is Instant Postum made-with-hot-milk.

POSTUM COMPANY, INC., P-N. H.-6, BATTLE CREEK, MICH.

We will be glad to send the physician who addresses us a special gift package containing a full-size package of Instant Postum, together with samples of other Post Food Products, which include Grape-Nuts, Post Toasties and Post's Bran Flakes. If you live in Canada, address GENERAL FOODS, LIMITED, Dept. P-N.H. 6, Sterling Tower, Toronto.

A New Water Test Comparator

For The Water Analysis Laboratory

The New Water-Test Comparator

A new Water-Test Comparator which eliminates the preparation of standard solutions, has been designed on the same principle as the permanent color standards pH Outfits, now so widely used.

Insert the color disc in the rack above the special Nessler Tubes, match the colors and read (directly) the parts-per-million.

Color Discs

			Range	
Color-of-Water Disc	#1	— 5	to 40	color unit Steps of 5
	#2	— 40	to 150	
Ammonia Nitrogen	#1	— 0.00	to 0.40	parts per million
	#2	— 0.50	to 1.6	" " "
Nitrite Nitrogen	— 0.0	to 0.025	" " "	
Nitrate Nitrogen	#1	— .00	to 1.0	" " "
	#2	— 1.5	to 10.0	" " "
Chlorine	#1	— .01	to 0.09	" " "
	#2	— 0.1	to 0.5	" " "
Total Iron	— 0.0	to 3.0	" " "	

The Fisher Illuminator is ideal for illuminating the Water Comparator or other laboratory apparatus

Price \$3.75 with blue bulb

(The color camera, in front of the Water-Test Comparator, is a pH determination outfit.)

The Water-Test Comparator with two special Nessler Tubes,
but without discs. . \$45.00

Color Discs \$12.50—\$15.00 each

THE BELL TELEPHONE SYSTEM IS ORGANIZED TO GIVE CONSTANTLY IMPROVED SERVICE . . .
QUICK, ACCURATE, EASY TO USE

What you want of the telephone . . . it is our business to give

An Advertisement of the American Telephone and Telegraph Company

WHEN you order a telephone, you want it put in promptly. During the last five years the average length of time needed to have a telephone installed has been cut nearly in half.

You want quick and accurate service, free from trouble. Good as the service was five years ago, today there are a third less troubles per telephone. During this same period there have been marked increases in the already high percentage of perfectly transmitted conversations.

When you make a toll call, you want a prompt, clear connection. Five years ago 70 per cent of all toll and long distance calls were handled while the calling person remained at the telephone. Today all but a very small per cent are handled this way.

The Bell System is organized to give constantly improved service.

Several thousand persons in the Bell Laboratories are engaged in research that improves the material means of telephony. The Western Electric Company, with plants at Chicago, Kearny, N. J., and Baltimore, specializes in the manufacture of precision telephone equipment of the highest quality. From its warehouses all over the country, it supplies the millions of delicate parts for Bell System apparatus.

The operation of the System is carried on by 24 Associated Companies, each attuned to the area it serves. The staff of the American Telephone and Telegraph Company is continually developing better methods for the use of these operating companies. Your telephone service today is better than ever before. The organized effort of the Bell System is directed toward making it even better tomorrow.

Perfection
Microscopic Slides

are of a new type and appeal to the busy technician and research microscopist.

These slides have a ground face at one end on which identification markings may be made. They are for use when it is desired to mark the slides in a permanent or semi-permanent manner.

The ground surface will permanently retain markings made with indelible ink. Markings made with an indelible pencil, lead pencil or ordinary ink may be removed by washing with water, but these markings are much more permanent than grease pencil figures on plain glass.

The ground glass surface eliminates the trouble caused by gummed labels, which soon become unsightly and in many cases increase the thickness of the slides to such an extent that two slides cannot be placed in a single groove of a slide box.

The slides are of medium thickness, having a thickness of from 1 mm. to 1.3 mm., measure 75 x 25 mm. and have a slight green tinge when viewed edgewise. The surfaces are plane, free from bubbles or other defects, and the edges are nicely ground.

The slides are inexpensive and are packed in boxes containing one-half gross. A sample slide will be cheerfully and promptly furnished upon application.

*Crane continuous flow bath, C 6262*

6' 6" x 33" of modern convenience

WITH hygienic medicine setting the pace, there can be no lull in advancing the designs and service of the fixtures which provide sanitation and convenience. Crane specialists in this field are constantly posting themselves on the latest requirements . . . and meeting them. Let this continuous flow bath serve as an example.

In its six and one-half foot length, and its thirty-three inch breadth, the patient can be at perfect ease, supported by a heavy canvas cradle, laved in water whose constant temperature is maintained by accurate thermostatic valves. More than the utmost convenience is represented in this bath. Like all Crane fixtures for hospitals and institutions, it presents the utmost in quality as well: the workmanship and careful choice of materials that have made Crane products synonymous with durability and service.

SAFE PASTEURIZATION *for the* SMALL PLANT

Note the compactness and cleanliness of this typical Cherry-Burrell small dairy lay-out.

ARE you familiar with what Cherry-Burrell has done and is doing to bring the safety of pasteurization within reach of the smaller cities and towns, the smaller dairies?

Cherry-Burrell offers these smaller plants efficient equipment, especially designed for small plant use, at prices that do away with any need for large investment. Boilers, sterilizing bottle washers, pasteurizers, coolers, bottle fillers and cappers and every other necessary item of equipment.

Ask us for detailed literature on the Cherry-Burrell line of small dairy pasteurizing equipment. And for our interesting folder showing Seven Plans for Small Dairies. It will interest you.

Name

Street Address

City.....State.....

"**SEQUELAE**" (seh-kwee-lee) is the doctor's word for the whole range of consequences and serious complications following certain illnesses. Weakened hearts, kidneys, lungs, defective hearing or eyesight and other physical impairments may be the Sequelae of many diseases.

There is a homely old expression, "not out of the woods yet", which fairly describes the condition of a patient who has successfully passed the crisis of a serious illness.

Your doctor will tell you that sometimes the Sequelae, or after-effects, are more to be dreaded than the disease from which you are apparently

recovering. Don't think him an alarmist if his orders are strict about not getting up from bed too soon, or if he makes a thorough physical examination after you think you are entirely well.

The Metropolitan health booklets tell in plain language how some of the Sequelae of diseases may be avoided. If anyone in your family is suffering or recovering from one of the diseases which may leave serious after-effects, send for the Metropolitan's booklet concerning it and learn just what you should know about the possible Sequelae. Address Booklet Dept. 8A0, and name the booklet you want. It will be mailed free.

COLDS break ground for pneumonia, influenza, or tuberculosis. Deafness, sinus infection, or chronic rheumatism, or a weakened heart may follow an ordinary cold.

TYPHOID FEVER leaves the patient more susceptible to other diseases and sometimes affects the heart and gall-bladder.

DIPHTHERIA may injure the heart or cause paralysis.

MEASLES may be followed by pneumonia, kidney trouble, loss of sight or hearing.

WHOOPIING COUGH may be followed by pneumonia or tuberculosis.

TONSILAR INFECTION may be followed by rheumatic fever or heart trouble.

SCARLET FEVER may affect the heart, kidneys or ears.

RHEUMATIC FEVER often seriously injures the heart.

HELLIGE COLORIMETRIC COMPARATORS

For Hydrogen Ion and Other Colorimetric Tests

Besides the regular use for hydrogen ion determinations, these comparators are used also for other colorimetric work, particularly in connection with water.

Special discs are used to show color of water, ammonium nitrogen, nitrite nitrogen, nitrate nitrogen, chlorine and total iron.

Bulletin No. 440 gives details of above mentioned comparators for hydrogen ion work, and Bulletin No. 442 gives details of the comparators for water testing.

Quick bacteria counts

THE FROST METHOD IS *faster*

FOR FIELD OR LABORATORY

WHEREVER time saving is important the Frost Little Plate method is recognized by bacteriologists as the fastest simple way of making an accurate count of the bacteria in milk.

The constantly growing demand for this equipment since the publication of the method in 1921 is due to the fact that, while reducing the total time required for the test to, at the most, a third of that necessary in the older plate methods, there is no loss of accuracy and no need for more specialized technique than is called for by previous standard counting practices.

There is also in the Frost method the additional advantage of economy occasioned by the substitution of microscope slides for Petri dishes and by the much smaller quantity of medium used.

For complete information on this equipment and a detailed discussion of the method ask for our free Bulletin 97-G.

Schooling Raises Pay

Statistics show that, on the average, high school graduates earn \$1.00 for every 72 cents earned by boys with merely elementary education.

"Dad, I want to get a job. Lots of rich men didn't go to school any longer than I have."

"My boy, you have heard about only the rare exceptions. You don't know how many millions of men have been barely able to keep body and soul together because they were only half educated and unable to compete with better trained men. You'd better go back to school."

©1930 M. I. I. Co.

MAYBE it is the boy next door—perhaps it is your own boy—who is eager, restless and ambitious, who would like to quit school and go to work. He is looking forward to the day when he will have more spending money and more independence.

He has read of self-made men who had but little schooling. He sees no reason why he could not do equally well.

Tell him that if he had a chance to talk to one of the big, self-made men of whom he has heard, he would probably be told, "While I was earning a place for myself in the business world I studied at night trying to keep up mentally with my old school friends—even those who went through college."

Before he is permitted to leave school it would be a great thing if he could talk to some man or woman in charge of employment for a big company. He would learn that the better educated boys and girls are given preference, from the outset, over those who quit school too soon.

In almost every kind of work; whether manual, mechanical, business or professional, higher wages and salaries, in the overwhelming majority of cases, are earned by the best educated and best trained.

Apart from the greater enjoyment of books, arts and science gained through education—and just as a matter of cold dollars and cents—education pays the best dividends.

THE AMERICAN TELEPHONE AND TELEGRAPH COMPANY PAYS ONLY A REGULAR, REASONABLE DIVIDEND TO THE 500,000 OWNERS OF ITS STOCK

They use it, they believe in it, they own it

An Advertisement of the American Telephone and Telegraph Company

THE Bell Telephone System is representative of the new type of ownership in American business, and of the responsibility to further the nation's welfare and prosperity which such an institution accepts.

Some 500,000 men and women, in nearly every town and city in the country, own the stock of the American Telephone and Telegraph Company. The average number of shares per stockholder is thirty. No single individual owns as much as one per cent of the total capital stock. The company pays only a regular, reasonable dividend, which it has not missed paying since its incorporation. Earnings beyond that go into the extension and improvement of the telephone service.

The Bell System is an American institution which consistently builds ahead of the communication needs of the day and year. Its construction program for 1930 requires the expenditure of approximately 700 million dollars.

The scope, speed and accuracy of its service is dependent on the constant research of more than 5000 scientific workers, new methods of operation and construction, and the co-ordinated efforts of more than 450,000 widely scattered employees. All its efforts are centered on giving the public a steadily improving telephone service at the lowest possible cost. This is the accepted responsibility of the Bell System.

For Children with PEDICULOSIS

This New, Effective Treatment

(See FREE offer below)

CUPREX is a new, quickly effective preparation, easy to use. Unlike others, it kills lice and nits both with one thorough application. Has no ill effects on hair or skin. Full directions are given with each bottle.

For cases where it is necessary to notify parents, we have prepared a standard Report Form, supplied in pads. The front

side tells the parent the trouble in as nice a way as possible. The reverse side outlines proper treatment with Cuprex.

FREE—We will gladly send to any Physician, Public Health Official or Nurse a pad of report forms and one 2-oz. trial bottle of Cuprex to use on a case. Simply use coupon.

MERCK & CO. INC.
Dept. H-1, Rahway, N. J.

Gentlemen:—Without cost or obligation to me please send me a pad of report forms and one 2-oz. bottle of Cuprex.

Public Health Depends on Water Analysis

The Water Analysis Laboratory needs the right apparatus to meet the abnormal demands of this season's water conditions.

We offer two pieces of apparatus which facilitate correct results.

Water Sample Case

—A Combined Bottle Holder and Ice Compartment—

Designed to maintain a low temperature during transportation and thus prevent bacterial growth. It is made of heavy galvanized iron with double insulated walls. A celluloid pocket inside the cover for holding records and history of samples. (Case holding more bottles can be made to order.)

Case with 4 two-ounce bottles - - - \$23.00

Water Test Comparator FOR CHLORINE

Eliminates the preparation of standard solution. Just insert Chlorine Disc No. 1 or No. 2 and match the colors (directly) parts-per-million.

Chlorine Color Disc, No. 1 — .01 to 0.09 parts per million

Chlorine Color Disc, No. 2 — 0.1 to 0.5 parts per million

Comparator with two
special Nessler
Tubes, but without
discs - - - - \$45.00

Discs - - - - - \$12.50 each

Ortho Tolidine Solu-
tion, 100 cc. - - \$1.50

Not one need die--- Not one need suffer

The results already attained in the fight to eradicate diphtheria prove that by applying the scientific knowledge and resources at the command of physicians not one child need die from this dreaded childhood disease—not one need suffer.

The educational work of the campaigns must be continued by physicians. Now—when the Diphtheria Incidence Curve begins its upward climb—is the time for immunization of all unprotected children.

In the struggle against disease, the House of Squibb has for many years offered to the medical profession a complete line of biological products, the finest that science, skill and painstaking care have been able to produce. It provides efficient service to Boards of Health and Clinics—serves communities as well as individual physicians.

A booklet giving complete information regarding Squibb Diphtheria Products will be sent upon request—just address Professional Service Department, E. R. Squibb & Sons, 745 Fifth Avenue, New York.

SQUIBB DIPHTHERIA PRODUCTS

◊
Diphtheria Antitoxin Squibb
—For prophylaxis and treatment.

◊
Diphtheria Toxin for Schick Test—To determine susceptibility to diphtheria.

◊
Diphtheria Toxin-Antitoxin Mixture—For active immunization of susceptible persons against diphtheria. Prepared from the sheep.

◊
Diphtheria Toxoid Squibb (Anatoxin Ramon) a non-toxic product for active immunization against diphtheria.

Quick bacteria counts

THE FROST METHOD IS *faster* FOR FIELD OR LABORATORY

WHEREVER time saving is important the Frost Little Plate method is recognized by bacteriologists as the fastest simple way of making an accurate count of the bacteria in milk.

The constantly growing demand for this equipment since the publication of the method in 1921 is due to the fact that, while reducing the total time required for the test to, at the most, a third of that necessary in the older plate methods, there is no loss of accuracy and no need for more specialized technique than is called for by previous standard counting practices.

There is also in the Frost method the additional advantage of economy occasioned by the substitution of microscope slides for Petri dishes and by the much smaller quantity of medium used.

For complete information on this equipment and a detailed discussion of the method ask for our free Bulletin 97-G.

"THERE IS NO SUBSTITUTE FOR FRESH MILK"

Certified Milk

production requires the finest type of stable for the cows. Here are some of the high spots:

Sunny—Big windows kept clean admit sun and air.

Easily cleaned—Cement floors easily swept and flushed—Metal piping partitions and fastenings.

Keep cows clean—The cowstands or lies on a clean floor, bedded with sanitary bedding. The droppings clear this and fall to the gutter behind and below (Hoard stall).

Keep cows comfortable—Individual drinking cups—Fresh water always available—Stanchions are movable or neck chains are loose.

OLD MEXICO!—the little known, the little understood. A land of mysterious origin and vast antiquity. Yet in many ways as new as tomorrow.

Come, just as this land is awakening. Before sightseeing buses crowd out the old-world open carriage. Even now the tractor crawls past the oxen and wooden plough. Find now, for yourself, the ruins of a civilization history has never chronicled, the Aztecs and Toltecs—the markings of Spanish Conquistadores, who with Cortez lashed this land for gold. Dine in the open garden-patio of Old World cafes before they are rebuilt for the Americano soon to come.

Vanta*

Baby Garments

No Pins No Buttons

Practically every VANTA* Garment has been designed to meet requirements and specifications of the medical profession. For years suggestions of doctors and nurses have been incorporated in these garments.

First came the plan for dressing babies for the first two years without pins and buttons—removing the real danger from both.

Then came VANTA* Self-Help Garments for wear after two years, teaching babies to dress themselves—training their minds.

VANTA* IRISH LINEN MESH

Fabrics, too, have doctors' approval. Now comes VANTA* Irish Linen Mesh Garments at price range of every mother. Doctors and nurses know the valuable properties of linen. VANTA* combines purest Irish linen thread with just the proper amount of lisle to remove harshness. Healthful in every respect.

All VANTA* Garments come in a variety of scientifically knitted fabrics including silk, wool, Irish linen mesh, rayon, sase and cotton, all fashioned carefully for tiny bodies.

*Trademark Registered U. S. Patent Office.

On request we will send our book, "Baby's Outfit," on proper care and dressing of babies, also prices and descriptive information.

*Tasty, wholesome
bananas are rich
in Vitamin C*

Vitamin C

helps build Sound Teeth

A most important paper gives the evidence. Read the address of Dr. Walter H. Eddy on "The Antiscurvy Vitamin C and Tooth Development," delivered at the Annual Meeting of the American Public Health Association, at Minneapolis, October, 1929.

While the preservation of children's teeth is important, the main consideration should be the development of sound teeth from the beginning.

As Dr. A. D. Blackader, editor of the Canadian Medical Association Journal, stated editorially in the issue of May, 1929:

"In directing our chief attention to

cleanliness of the teeth, we are trying to put an attractive superstructure upon a faulty foundation."

In "The Newer Knowledge of Nutrition," Dr. E. V. McCollum says:

"The development of sound teeth, capable of resisting the destructive agencies, is essentially a dietary problem."

Dr. Eddy has defined this problem, showing that a major tooth-forming factor in the diet is Vitamin C. The banana is a good source of this vitamin.

The continent that became a neighborhood

An Advertisement of the American Telephone and Telegraph Company

THROUGH slim wires etched against the sky... through cables laid in the earth under cities and fields... millions of Americans, miles or days' journeys apart, speak to each other as readily as though they stood face to face.

Over her telephone, a housewife in a Wisconsin town inquires about a dress pattern from a friend who lives nearby. Over his telephone, a business man in Philadelphia talks to another in Denver. Over her telephone, a mother in Kansas asks her son at college fifty miles away if he will come home for the week-end. Over his telephone, a cabinet member in Washington gives instructions to an assistant in Seattle. Regardless of distance and the complexity of modern living, they talk directly and immediately with any one, anywhere, at any time they choose.

The function of the Bell Telephone System is the vital

one of making it possible to maintain social and business contacts in cities that contain many times more people than this nation once boasted... in a neighborhood which the Census reports to hold 127 million people.

Year after year from its beginning, the Bell System has increased its facilities, its personnel and its usefulness. Looking ahead and planning for the future, it has forwarded the growth of this nation by meeting its communication needs fully and economically. Today it overcomes the hindrances of distance and time... and unifies a civilization geared to the habit of instantaneous communication. Because it serves all who call on it, by enriching their lives and helping to make their enterprises more successful, the telephone plays an increasingly useful part in the every-day activities of the American people.

Perfection
Microscopic Slides

are of a new type and appeal to the busy technician and research microscopist.

These slides have a ground face at one end on which identification markings may be made. They are for use when it is desired to mark the slides in a permanent or semi-permanent manner.

The ground surface will permanently retain markings made with indelible ink. Markings made with an indelible pencil, lead pencil or ordinary ink may be removed by washing with water, but these markings are much more permanent than grease pencil figures on plain glass.

The ground glass surface eliminates the trouble caused by gummed labels, which soon become unsightly and in many cases increase the thickness of the slides to such an extent that two slides cannot be placed in a single groove of a slide box.

The slides are of medium thickness, having a thickness of from 1 mm. to 1.3 mm., measure 75 x 25 mm. and have a slight green tinge when viewed edgewise. The surfaces are plane, free from bubbles or other defects, and the edges are nicely ground.

The slides are inexpensive and are packed in boxes containing one-half gross.

A sample slide will be cheerfully and promptly furnished upon application.

When nature says "*that's that!*"

MEMBERS of a generation that burns the candle at both ends . . . they suddenly discover that abused bodies *can* talk back. Reluctantly they see that they can go no further on the false energy of stimulants. They realize that a breakdown, brought on by driving, heedless living, is imminent. And so they come to you.

Often one of the most trying phases of such cases is inducing the patient to give up caffeine stimulants. For habits love life—and the caffeine habit, particularly, is a vigorous one.

But hundreds of physicians have found that Postum is a real help. For Postum, hot, fragrant and appetizing, has a gracious way of edging drinks containing caffeine off the menu. And Postum is entirely harmless. It is made only from sun-ripened whole wheat and bran, roasted to a delectable brown and slightly sweetened.

Patients take to Postum readily for it is a wonderful drink in its own right. It is so good, so delicious that it is a mealtime favorite with two and a half million families.

Instant Postum made-with-hot-milk is a valuable addition to the diet in cases of under-nourishment. Postum is a product of General Foods Corporation. © 1930, G. F. CORP.

You know how often *the block resembles the chip*

ROBERT SMITH Jr., age three, is caught playing with a box of matches. He yells as only three-year-olds can yell when you take them away from him. But he quiets down when you give him something harmless instead.

Robert Smith Senior, age 43, is of much the same stamp. Worn out and all in, he comes to you, asking for health. You find that he's been overworking, borne up by the false energy of stimulating drinks. You tell him to get back to normal living . . . and if you advise him to give up caffeine, you know how much he acts like his three-year-old son.

He protests, if not to you, to himself. He wants that hot, pick-up drink—or something to take its place.

In cases like this, thousands of physicians prescribe Postum. For Postum fills the bill perfectly. It offers all the warmth, fragrance and well-being of drinks containing caffeine—yet none of their harmful effects.

Postum is made from whole wheat and bran, deliciously roasted, and slightly sweetened. It is so good that two and a half million families serve it regularly.

The Giant and the Pygmy

© 1930 M. L. I. CO.

EITHER from your own personal experience or from observation you know how miserable one can feel when suffering from a cold. Of course you know some of the causes—chilling drafts, wet feet, over-fatigue, balky digestion, or an invading germ. You know it is harder to fight a cold when you are run-down. Keep yourself fit.

For the sake of your own personal comfort you want to get rid of a cold in the shortest possible time. For your own personal safety and that of your friends you ought to get rid of a cold in the shortest possible time.

There are many different kinds of colds—hard to distinguish one from the other. All of them are threats and one leads to another.

The original cold, if not promptly cured, breaks down resistance and is sometimes followed by a second cold more stubborn and oftentimes more treacherous than the first. The mucous membrane of the nose and throat is so weakened by Cold

No. 1 that the way is opened for dangerous germs to enter.

Cold No. 1 is the Pygmy that crawls through the keyhole and unlocks the door for Cold No. 2, the Giant. In fact, to carry the picture further, the Pygmy Cold, which may be nothing worse than snuffles, a slight cough, a bit of an ache or a pain, may be followed by any one of several Giant Colds—influenza, pneumonia or tuberculosis.

Take no chances the next time that symptoms of catching a cold are shown by you or someone in your family. Consult your doctor and dispose of the Pygmy quickly, before he can open the door for the Giant. At such a time a skilful doctor is your best ally and you will be wise in following faithfully his orders.

Metropolitan Life Insurance Company will be glad to mail free, its booklet, "Just a Cold? Or"—to anyone who requests it. Address Booklet Department 12A0.

**VAN SLYKE CONSTANT VOLUME
BLOOD GAS APPARATUS**

For the determination of CO₂, CO and O₂, in Blood and Other Solutions, Micro Kjeldahl Determination of Nitrogen, Urea, Etc.

The fine glass blowing, vacuum tight grinding, accurate engraving and excellence of mechanical workmanship of the Van Slyke Constant Volume Apparatus made in our own shops is evident and much appreciated both here and abroad.

Of equal importance, but not so evident, are the many faithfully executed details of Dr. Van Slyke's specifications and verbal instructions.

Far from being details of minor importance they are actually essentials. They must be complied with—correct results are not possible otherwise.

Every stock Van Slyke Apparatus is made with the same care as though intended for Dr. Van Slyke's personal use.

Modern Bakers are Magicians

*with Flour, Eggs,
Butter, Milk and
Sugar*

THIS is one of the advertisements of The Sugar Institute, appearing in newspapers throughout the country. In order to keep the statements in accord with modern medical practice, they have been submitted to and approved by some of the leading authorities in the field of human nutrition in the United States.

IF IT were not for those dainty cookies, wafers, sweet crackers and cakes made by the great baking companies of this country and sold at grocery stores everywhere — what would ladies do at their teas and bridge parties — what would we do for desserts?

Alluring indeed are the creations of these bakers. And the marvel of it is that they come to us oven-fresh. What a tribute to the careful way they are made, packed and delivered.

There is a place in every balanced

diet for these inviting inexpensive cookies and cakes. They round out the meal and make everybody satisfied and happy.

Too many of our meals are lacking in enjoyment because sugar has been left out. Try a dash of pure cane sugar in the essential foods, such as vegetables, fruit and cereals, and see how much better they taste. Doctors and dietitians heartily recommend this use of sugar as a flavor. The Sugar Institute, 129 Front Street, New York.

A Study of Cultures of *Monilia* Isolated from Sputum*

RUTH GILBERT, M. D., F. A. P. H. A., AND WILLIAM
M. GROESBECK

*Division of Laboratories and Research, New York State Department of
Health, Albany, N. Y.*

ALTHOUGH species of yeast-like organisms were associated with thrush as early as 1839, the relation of fungi to human disease has been given far less attention than similar phases of bacteriology. The wider interest in pathogenic bacteria has probably been aroused by their greater frequency as incitants of systemic disease. In temperate climates, few of the serious diseases of man or other animals have been shown to be due to fungi. Nevertheless, the high mortality of the systemic form of blastomycosis and the similar type of infection known as coccidoidal granuloma, occurring in the San Joaquin Valley in California, illustrates the marked pathogenicity of certain species of these organisms for man. Among plants, many of the most destructive diseases are due to fungi. The economic importance of the numerous blights, smuts, and rusts is too well known to need emphasis.

Castellani's¹ extensive investigation of mycotic infections in man, particularly in the tropics, has demonstrated their wide distribution, the variety of lesions induced, and the number of species involved.

The recent attention paid to mycoses of the skin, especially of the feet, which have been found in such a large percentage of college students and others using the shower baths in clubs or gymnasiums, has stimulated interest in mycotic infections in general. The relative frequency, in Wisconsin, of pulmonary lesions due to *monilia* as shown

* Read before the Laboratory Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

by the work of Stovall¹ raises the question of whether infections of this nature may not be more disseminated in other parts of the country than statistics indicate.

Of the large number of specimens of sputum received at our laboratory, extremely few are accompanied by requests for an examination for fungi. Most of those containing these organisms have first come to our attention in the course of the routine examinations for tubercle bacilli, and cultures are occasionally submitted for identification from other laboratories.

Strains of monilia pathogenic for white rats have been isolated from the sputum of 11 patients. The clinical histories of 2 are especially interesting. The first was a woman 51 years of age who had been acutely ill for about 6 weeks. Tuberculosis was suspected. The symptoms recorded were considerable coughing; a large amount of thick, mucilaginous sputum, almost constantly blood-streaked; very little fever; severe pain in the lower chest; some dullness; a few rales; and at times delirium. In a series of sputum specimens examined in a local laboratory, no tubercle bacilli were found, but a culture of monilia was isolated. This culture and additional specimens from the patient were sent to us for further study. A few acid-fast bacilli were seen in one stained preparation made from the sputum, but no others could be found in any of the specimens, even upon repeated examination. The patient finally began to improve, and about a year later seemed in perfect health.

The second was a man of 66 who had been superintendent in a burlap bag factory where he was exposed to dust from the cleaning of coarse fiber used in weaving. For several years he had had symptoms resembling those of tuberculosis. He had visited various sanatoriums and, although a large number of sputum specimens were examined, no tubercle bacilli were found. In one sanatorium, a diagnosis of sporotrichosis was said to have been made, based on the finding of the organism in the sputum.

At the time the first specimen of sputum was sent to our laboratory, the patient had been acutely ill for about 6 months, a lung abscess and empyema having developed. Following a series of severe hemorrhages, a rib resection was made and the abscess drained. After this treatment no more hemorrhages occurred, but profuse drainage and considerable coughing continued. The general condition of the patient deteriorated until he died 19 months later. An autopsy was not secured. Cultures of monilia were isolated from 3 of the 6 specimens of sputum submitted at intervals during a period of 11 months. No acid-fast bacilli were found in any of them, but a guinea pig

inoculated with one of the specimens from which monilia were isolated developed generalized tuberculosis.

The information concerning the clinical manifestations in the other cases is more limited. The data available may be summarized as follows:

A man of 32 with a clinical diagnosis of pulmonary tuberculosis.

A boy of 17 who had had an appendectomy 3 months prior to the development of a pulmonary abscess at the base of the right lung; coughing, expectoration, and pain were said to be the predominating symptoms.

A man 72 years of age with a cough and a slight rise in temperature.

A woman of 60 with chronic bronchitis, laryngitis, and pharyngitis, and a considerable amount of frothy mucous sputum; she had a history of cholecystitis of over 2 years' duration. Four months before the receipt of the first of two specimens from which monilia were isolated, the patient was acutely ill with pneumonia followed by pleurisy and jaundice, and type-II pneumococci were isolated from a specimen at that time.

A farmer 34 years of age having acute pleurisy with effusion.

A laborer-mechanic of 35 having had chronic bronchitis, rheumatism, and chronic myocarditis for 10 years following war service.

A woman of 28 with bronchitis of a few weeks' duration.

A woman mill worker visited a clinic for a chest examination; the attending physician found no evidence of tuberculosis, but requested the examination of a series of sputum specimens.

A man of 40 concerning whom no history has been obtained.

Monilia pathogenic for rats have been isolated also from the exudate from 2 cases of thrush and from 1 of vaginitis; and from the feces of a patient with a history of diarrhea of 8 months' duration and recovery following treatment with bismuth and potassium iodide.

In morphology, the monilia studied resemble yeasts (see Figures I and II). The cells are elliptical and reproduce by budding, while short hyphae are often noted. No ascospore formation can be demonstrated.

The cultures grow readily on the usual laboratory mediums. On agar, the growth is thick and creamy with a tendency to coalesce. Gelatin is not liquefied. The fermentative reaction with different carbohydrates has been found to vary. All of the strains studied ferment dextrose and most of them also saccharose and maltose. Dextrose broth has been found to contain ethyl alcohol after representative cultures have grown in it for 4 days.

All of the cultures have proved pathogenic for rats, and those tested have been found pathogenic for rabbits also. By intravenous inoculation, one-twentieth, or sometimes less, of the 24-hour growth on an agar slant is usually fatal for white rats and small rabbits in from 1 to 5 days. Adult rabbits may survive a single inoculation, but

FIGURES I AND II—A 24-hour culture of monilia on dextrose agar. Stained with dilute carbol fuchsin. $\times 710$ diameters.

are killed by repeated doses. If white rats live for from 3 to 5 days following an intravenous inoculation, the lesions in the kidneys are characteristic. The surface of the organ is profusely dotted with raised yellowish white areas about 1 mm. in diameter. Sections of the organ (see Figures III to X) show a severe, extensive

nephritis. The cortex is almost entirely destroyed, only a few islands of convoluted tubules of relatively normal appearance remaining. The majority have undergone granular degeneration with hemorrhage and mononuclear cell infiltration. The glomeruli are extensively involved, some showing precipitated albuminous material in the glomerular spaces, others extensive hemorrhage or hyaline necrosis. The medulla is hyperemic and edematous, but the large masses of necrosis found in the cortex are absent. When Gram-Weigert stain is used, numerous colony-like masses of fungi are found throughout the kidney, but particularly in the cortex. The cellular elements appear as globules, varying in size from approximately 1μ to 12μ , and varying from light violet to intensely stained forms, with small and large intracellular granules. Numerous short mycelial filaments, some of them about 30μ in length are seen.

FIGURE VII—Stained by Gram-Weigert method. $\times 100$ diameters.

FIGURE VIII—Section of kidney of rat (M. 3980) dying 3 days after inoculation with monilia. Eosin methylene blue stain. $\times 70$ diameters.

FIGURE IX—Eosin methylene blue stain. $\times 70$ diameters.

FIGURE X—Eosin methylene blue stain. $\times 840$ diameters.

In the myocardium and liver, numerous focuses of necrosis with slight hemorrhage and mononuclear cell infiltration are found. Evidence of encephalitis with perivascular mononuclear infiltration, and an occasional necrotic area resembling those in the other organs mentioned may be noted in the brain. Sections of the lung show congestion and edema with numerous polymorphonuclear leucocytes in the alveolar exudate, presenting a picture of early pneumonia. Usually, cultures of the organisms can be readily isolated from these organs or from the heart's blood.

Since some of the lesions appeared to have originated in minute infarcts and since the monilia cells are much larger than most bacteria, it seemed desirable to determine whether the injuries to the tissue had been primarily due to mechanical plugging of the capillaries. Animals were therefore inoculated intravenously with cultures of baker's yeast, *Saccharomyces cerevisiae*, which has cells about the same size as those of monilia, or perhaps a little larger. Culturally and morphologically, yeasts resemble monilia, except that ascospore formations can be demonstrated. White rats, guinea pigs, and rabbits receiving intravenous inoculations of massive doses seemed uninjured.

Proof was not obtained that the strains of monilia isolated from the sputum were incitants of pulmonary lesions in the patients from whose specimens they were obtained. Probably, in some cases at least, they were secondary invaders. Judging from the behavior of the similar, if not identical, organisms found in thrush, the vitality of the individual may need to be markedly lowered before infection occurs. It is possible also that some of the pathogenic species of monilia in the sputum specimens may have been derived from unobserved lesions of thrush in the mouth, throat, or bronchi.

The finding, in large numbers, of organisms capable of inducing such characteristic lesions in laboratory animals in only a small percentage of sputum specimens examined, and the fact that the specimens containing them have, in most cases, come from patients presenting some evidence of pulmonary disease would seem to warrant an investigation of the etiological relation of the organisms to any disease process that may be present. Such a study can of course be successfully made only in laboratories where there is opportunity for repeated observation of the patient, and for a post-mortem examination.

Standards for Public Bathing Beaches and Wading Pools*

BEFORE proceeding with the discussion of the two topics assigned to us for special consideration at the 1928 meetings of the Conference of State Sanitary Engineers, and of the Public Health Engineering Section, your committee wishes to call attention to the need for special precautions to prevent the spread of infectious skin diseases of the feet at swimming pools and other public bathing places.

FOOT DISEASES

Although such diseases are not reportable, and their prevalence is not a matter of official record, unofficial reports of the occurrence of ring worm, toe itch, toe scald, fungus foot, papilloma, and similar infections at pools and beaches in various parts of the country are becoming more and more frequent.

Most, if not all, of these foot diseases are caused by a fungus which is spread by infection of the floors of dressing rooms, etc., at pools, bath houses, gymnasiums, and other places where persons go barefoot. While control methods have not been completely worked out, the following preventive measures will prove useful in checking the spread of these diseases:

1. The feet, and especially the toes, of all bathers should be inspected regularly, and those persons showing infection should be excluded from the pool and dressing rooms and advised to consult a skin specialist. The disease may show around the base of the nails or between the toes as raw open sores—the sodden type; as small or large blisters—the vesicular type; or it may resemble eczema. The type which the disease exhibits may change from time to time in the same patient, depending on circumstances.

2. Wash all floors, benches, and stools in dressing rooms, diving boards, out-of-water portions of ladders or steps, rubber mats, etc., daily with a strong solution of chlorinated lime or chlorinated soda. It is known that the fungus will grow readily on silk and cotton goods and on leather, and it is believed that it will also grow on damp wood;

* Report of the Joint Committee on Bathing Places of the A. P. H. A. and the Conference of State Sanitary Engineers, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

so special attention should be paid to disinfection of any woodwork with which the feet of bathers may come in contact. Canvas mats or pads should be abolished.

3. Take precautions to insure that there is no exchange of unsterilized towels, suits, bathing slippers, etc., among bathers. All suits and towels should be thoroughly sterilized by boiling before being dried for reissue, as recommended in the last report of this committee.

BATHING BEACHES

The committee would again call attention to the sanitary requirements for public bathing beaches recommended in paragraphs II, III, XII, XIII, XIV, XIX, XX, and XXI of its report for 1926,* entitled "Standards for the Design, Construction, Equipment, and Operation of Swimming Pools and other Bathing Places."

As stated in paragraph III, A, the committee is of the opinion that "It is very desirable that the bathing waters at public bathing places on natural streams, lakes, and tidal waters should be of the same standard of bacterial quality as is required for swimming pools." It is recognized, however, that the strict application of swimming pool water standards to all public bathing waters would probably not be practicable at present. Furthermore, since there is not now available any sufficient volume of data as to the quality of waters now used for bathing, nor any sufficient record of the causation of disease by bathing in moderately polluted waters, your committee feels that any definite standard of bacterial quality which it might propose would be purely empirical.

In the case of swimming pools it was entirely fair to set up a high standard of bacterial quality, since effective methods were available by which such quality could be maintained at a reasonable cost. The bathing beach problem is distinctly different. In certain instances it may be feasible to treat the water at the beach satisfactorily with chlorine or other disinfectant. In the majority of instances, however, to set up and attempt to enforce a high standard of bacterial quality would mean that we would be forced either to condemn many waters now used for bathing, or to attempt to reduce the pollution by elimination of the sources or by treatment of sewage discharged therein. As in many cases there has been a considerable capital investment at these beaches, not only in bath houses and bathing equipment, but also in amusement facilities, any attempt at condemnation, except following an epidemic traceable to the pollution of the waters, would meet with strong opposition both from the public, who have been accustomed to

* *A. J. P. H.*, XVI, 12: 1186 (Dec.), 1926. For 1927 Report, see *A. J. P. H.*, XVIII, 2: 194 (Feb.), 1928.

bathe regularly at these beaches, and from persons whose investment would be wiped out by their closing. On the other hand, the reduction of pollution usually means a large expense for sewage treatment and considerable delay while such treatment works can be planned, financed, and constructed.

It would seem to your committee, therefore, that while it is entirely legitimate to use pollution of bathing beaches as an argument in a program for a clean-up of public waters, the bathing beach problem is one which should properly be worked out by local and state authorities for the best interests of all parties concerned in each particular locality, unhampered by any empirical standards.

In a swimming pool the major danger to health of bathers comes from fresh secretions introduced into the water by other bathers. At a public bathing beach where a large volume of water is available for dilution, the danger of infection by such personal discharges is very much reduced, and the major health hazard becomes that of pollution of the water by sewage. The potential danger to health from bathing in water at any particular beach can only be determined by a complete survey, in which dilution of the polluting sewage, and the effect of tides, winds, and other factors in producing currents, are given full weight in the interpretation of the results of bacterial and chemical analyses of the water. In such an interpretation it must ever be borne in mind that the time-travel-distance factor of polluting waters is of paramount importance from a public health viewpoint. Direct pollution by fresh sewage from nearby sources, even though relatively small in amount, is potentially more dangerous than pollution by a much greater volume of sewage some distance away. It should also be recognized that a bather is much less likely to take into his mouth and swallow salt water than fresh, and for this reason the same degree of pollution may be potentially less dangerous at the sea-shore than at a bathing place on an inland stream or lake.

WADING POOLS

With increasing attention paid to the sanitation of swimming pools throughout the country, the attention of many sanitary authorities is being attracted to the need for improvement in the sanitation of the numerous shallow wading pools which have been installed for use of children in public parks and playgrounds. Early in the summer, your committee sent out a questionnaire asking the opinion of the various state sanitary engineers as to the advisability of attempting to control the sanitation of these pools, and as to what standards of water quality, cleanliness, etc., it would be practical to establish. Replies

have been received from only 12 states, an insufficient number to enable your committee to determine the consensus of opinion of the health authorities of the states on these questions, and make any definite recommendations. The replies already received, however, indicate that:

1. It is both desirable and practicable to establish a system of supervision over sanitation of public wading pools similar to that now exercised by public health authorities over swimming pools.

2. It appears inadvisable at present to require the same standards of water quality for very shallow pools used for wading only as are required for swimming pools.

3. For administrative purposes a distinction on a basis of maximum depth of water should be established between swimming pools and wading pools.

Men's Clothing

DR. BORLAND says: Take the question of cleanliness. The average woman wears light fabrics, which quickly show the dirt, but are easily and frequently cleaned. Have you ever considered how long a man's suit goes without being *thoroughly cleaned*? Men's clothes actually come into contact with and absorb more dirt than women's; but it does not show so much because of the darker color of the cloth. *The dirt is there all the same, although not seen*, and where there is dirt you will find germs. Consider hygiene in a broader sense. The many layers and heavy, thick material of men's garments make them thoroughly unsatisfactory from a health point of view. What chance has sunlight or fresh air of gaining access to the body? The perspiration, instead of evaporating freely with an inappreciable odor, is retained by the inner and outer layers of clothing. They become clammy and clammy, giving off an unpleasant and unhygienic odor. These damp, clammy clothes are also responsible for many of the so-called summer colds. What are the remedies? Changes can only come about by desire, thought and action. Men should realize their conservatism in dress and the need for more progressive ideas.—Dr. Vynne Borland, quoted in *Med. Off.*, Sept. 21, 1929, p. 135.

Need for Cancer Morbidity Statistics*

FRANCIS CARTER WOOD, M. D.

*Director of the Institute of Cancer Research, Columbia University,
New York, N. Y.*

TO a great extent the only available large scale statistics on cancer are those based on death certificates. These possess, as everyone knows, certain uncorrectable errors due to lack of accuracy in the primary documents. Such cancer death records, even with all possible corrections, are of but little value in the practical evaluation of the results of treatment, or lack of treatment, for any given individual with cancer; nor will any possible increase in accuracy of ordinary death records as at present made furnish such information.

The reports of the U. S. Bureau of the Census can rise no higher than the source of information, which is a death certificate. That these records may err by some 30 to 40 per cent may seem astonishing to statisticians, but not to pathologists. Full information on the matter has been in print for years, and Wells has recently again called attention to it. The only method of obtaining correct statistics is the basing of all diagnoses on autopsies. With the present attitude of a large proportion of the population, this is obviously impossible, and unfortunately even in so advanced a country as Switzerland which, as Hoffman has pointed out, has reached in all probability an approximate maximum rate for cancer in a white population, that is, some 125 to 130 per 100,000, there has been a recent check placed on autopsies. Unquestionably therefore the Swiss cancer rate will fall in the future.

These facts are also reflected in the great differences which exist between the cancer death rates in the larger cities with high grade hospitals, and those of the rural districts. The differences are just as striking as are the differences in the cancer rate of, say, Denmark and Switzerland and that of the United States.

As I have said, the statistical analysis of deaths cannot rise higher than the accuracy of the certification by the physician; so the country's cancer death rate is a reflection of the diagnostic accuracy, or rather inaccuracy, employed in making such reports. To the layman it may seem strange that a patient can die with cancer and yet have

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

no symptoms of the disease; yet every pathologist knows that this is not only possible, but not infrequent. For example, in the last two years I have seen 6 such patients autopsied in which no possible diagnosis of cancer could have been made before death. In one of these, two expert surgeons examined the patient with the greatest care and stated definitely that certain symptoms and suspicious bone changes could not be due to carcinoma of the prostate. Nevertheless, at autopsy the only carcinoma which was found was in the prostate and in the bones. The type in the bones was that of a prostatic carcinoma.

Another similar case without the bone changes entirely escaped diagnosis for that reason and was only shown to have carcinoma of the prostate at autopsy. While small tumors like these are not always the immediate cause of death, they may impede the flow of urine, inducing back-pressure on the kidneys with damage of their function, and either death from uremic disturbances or secondary infection.

Of two other illustrative cases there was one in which several operations were done to relieve adhesions between the intestines. The patient finally died of intestinal obstruction and a carcinoma of the ileocecal portion of the intestine was found. It was a diffuse growth and could not possibly have been felt by the surgeon who did the operations. It had no immediate connection with the cause of death, but unquestionably the patient's symptoms were due to this growth, and she would not have died unless the growth had been present.

In another instance a case of carcinoma of the stomach was not correctly diagnosed during life, though the patient was under observation for a number of months and every diagnostic facility used which a large metropolitan hospital could offer. In two other cases wholly unsuspected metastatic melanomata were found only at autopsy in the viscera. In one the history recorded the fact that a mole had been burned out of the skin of the back with radium four years before. In a second a small perforating ulcer of the foot was observed clinically but there was no evidence that this was of a malignant nature; yet at autopsy melanotic tumors were found in the heart muscle and elsewhere. Evidently tumor particles from a small plantar melanoma had been massaged into the circulation by the patient walking on the foot.

These 6 recent examples occurring in the course of only about 200 autopsies illustrate clearly enough the absolute impossibility of diagnosing a certain proportion of instances of cancer without autopsy. Unquestionably a large number of patients die with cerebral, pulmonary and abdominal carcinosis in which no diagnosis of the disease is made.

The constantly increasing crude rate in the United States is admirable evidence that the ability to cure the individual patient is so small that it makes no impression on the general trend of the disease, but when it is realized that only one-fifth of the cancer cases in a large city that apply to a general hospital are in a sufficiently early stage to warrant operation for the cure of the disease, it will be immediately realized that it is not surprising that the best modern treatment has had no effect on the disease. As a matter of fact, to say that 20 per cent of the patients who enter a hospital are operable is certainly a very optimistic exaggeration of the conditions applying all over the country.

In rural districts practically no cases come in time for curative treatment. This situation is due in part to the extreme difficulty of the diagnosis of the disease already referred to, in part to the gross ignorance of the patient, and in part to the lack of modern training of a considerable proportion of the medical profession. Again, the activities of quacks, mental healers and others who criticise the methods used by the medical profession to treat cancer, play a part; and often such irregular healers urge patients to follow a course quite different from that advised by the physician whom the individual may have consulted.

At present the tendency is not to speak of the cure of cancer, but rather of its arrest. The reason for this change in phrase is the fact that a careful study of large series of treated patients shows that late recurrences may take place 8 and 10 years after an operation; and that a person who has once had a cancer is by no means prevented from having a second, and possibly is more likely to have a second. Hence the tendency is to consider operative or other treatment as palliative rather than curative.

In order to estimate the palliative value of any type of treatment, the expectation of life of the untreated case must be known with some accuracy. This is not a simple arithmetic average of the survival period. That assumes that the term of existence of that sample of the population having cancer follows a strictly Gaussian probability curve, whereas in fact the curve is probably highly skewed in man as it is in animals bearing tumors. Figure I shows this. Hence some effort should be made to determine the mode in addition to the simple arithmetic mean.

In order that such data may be practically useful, age groupings are essential, and what is still more important is some information as to the site of the growth, its size when discovered, and its gross and microscopic characteristics. Without this information any prognosis

FIGURE 1—The curve shows the time of occurrence of death in 1,000 rats of the same strain inoculated with the Flexner rat carcinoma (FRC). The time intervals are weeks. The average survival period is obviously 8 weeks. The mode is 5 weeks. The weighted mean taken by multiplying the number of deaths in each group by the weeks practically corresponds with the mode in this tumor, but this is an accidental agreement as in other tumors the weighted mean differs from the mode. The dotted curve represents the deaths of *Drosophila* eggs after exposure to X-ray. It is merely included to show that curves similar to the tumor death curves are obtained by the action of another lethal agent on another biological material. The coördinates in this case should be the percentage of the survivals and amounts of X-ray.

as to the results of treatment of any type of tumor is impossible. As an example, selecting a site where tumors are external and should be diagnosed easily and early, it has been found that some tumors of the female breast, though very small, are very frequently fatal. These are the small celled tumors in fat women, especially when the tumor is in the mesial aspect of the breast. The tumor is not noticed early because of the bulk of the fat which surrounds it. It metastasizes rapidly because of the small size of its cells, and the path which these cells follow is directly back into the thorax, thus involving the mediastinum and the lung at a very early date. Such metastases are not removable by surgery nor curable by X-ray or radium.

On the other hand, the rapidly growing, morphologically highly malignant tumor in a thin woman in the outer half of the breast, composed of large cells, or of cells which make mucus, will be diagnosed so easily that there will either not be any metastases along the lymph channels into the lymph nodes of the axilla or, if such an occurrence does take place, the large cells will be caught in the lymph nodes and held there for a period. These patients are the favorable type and form the majority of those who survive their operative treatment over long periods. Every surgeon has such cases living ten, fifteen and twenty years after operation.

That the mechanics of the situation are important is evident from the fact that the mucoid cancers of the breast, which form sticky masses from which the cells escape with great difficulty, give a very high percentage of permanent cures. Unfortunately this type occurs in the breast only in about 1 per cent of the total cancers of this region.

If this Association is to do anything to improve this sorry situation which now exists in the treatment of cancer, it should stand squarely behind making cancer a notifiable disease. If this could be done, the situation would be benefitted in a variety of ways.

The making of diseases notifiable has hitherto been to protect the community from such individuals as have infectious diseases. Such reason does not apply to cancer. The importance of making this disease notifiable is to protect the individual from a purely personal and, unless promptly treated, inevitably fatal condition.

Physicians on the whole are rather fed up with the general statement of propagandists that 1 woman in 5 and 1 man in 8 of those dying between the ages of 45 and 65 will pass on from cancer. They are only mildly interested in the fact that cancer is now second to heart disease in the list of causes of death. What they do want to know as quickly as possible is what to say to the individual who has a cancer. For example, does any form of treatment really prolong life? We can answer this in a positive way. For those who come with cancer in an exceedingly early stage, surgery, radium and X-ray have unquestionably prolonged the lives of many for many years, so long in fact that it is proper to speak of a "cure." But at least 80 per cent of those who consult a physician are entirely beyond cure. What shall be done?

Today we have no reliable evidence as to the natural duration of the disease in different sites, and of the different types which will permit a physician to make a definite statement. For example, in a case of cancer of the rectum, will a simple palliative operation give the

person more comfort and prolong his life for a longer period than will palliative treatment with X-ray or radium? It is generally held by surgeons that a colostomy relieves pain and enables a patient to live for a considerable time in much better condition than if no such operation is done, and it is possible to say to the patient that considerable statistical evidence exists for believing that the average patient with untreated cancer of the rectum lives only about 26 months. But how does he live when untreated? We know roughly that he generally lives in abject misery. The person with a colostomy is much more comfortable.

The patient as an individual is not interested in the average length of life but how long *he* is going to live. If he has a diffuse infiltrating small cell carcinoma of the rectum, will he live a shorter time than a patient with a colloid carcinoma? No facts, but only general impressions, are available. If he has a colloid carcinoma, should he avoid a dangerous and extensive operation and fall back upon X-ray and radium?—or had the risk of the operation better be disregarded, to take instead the chance of permanent arrest of the growth, in case its removal is possible, rather than to attempt palliation by radiation methods?

The physician is daily asked to decide whether a patient with a doubtfully operable cancer of the breast will live longer with operation plus post-operative radiation, or will do better to avoid operation and rely upon X-ray and radium palliation. It is evident that these questions can only be answered if we have carefully collected statistics of the length of life of untreated cases which have been observed under conditions which will record the type of tumor, the X-ray demonstration of possible metastases and other facts which determine more than the mere presence of the growth—the natural duration of life under the particular circumstances. Now is the time to get such figures. In a few years all patients will get some form of treatment.

I do not for one minute suggest that these criterions will be available in this generation, but if only one state could be induced to make a beginning, facts would shortly be collectable. A good illustration of the necessity of such figures can be drawn from a collection in an extensive and valuable paper by Janet Lane-Claypon. The learned author states that "the study of late results in relation to the microscopical characters of the growths reveals no significant difference in the survival rates for growths of highly cellular type and those of scirrhus type." Yet undoubtedly there are differences. "The results of operation in cases of adenocarcinomata are more favorable than of either of the above form and those obtained with duct and

colloid cancer are decidedly better. The samples of these latter varieties are however very small."

These conclusions are based upon the study of nearly 2,000 cases of cancer of the breast with pathological reports. The difficulties, however, of accurately classifying the material, owing to the variability of the pathological reports and the clinical records, is acknowledged, and some of the samples are so small that studies of more cases will be necessary before definite results can be obtained. In other words, even in so laborious an investigation, backed by the authority of the English Government, conclusions are of necessity drawn in such general terms that they are of relatively little applicability to the individual patient. Yet daily the physician has to advise the afflicted patient.

There are, on the other hand, individual collections, mostly from hospital material, which cover certain points, among them length of life of treated or untreated cases, etc.; but of course it is well known that a hospital population does not represent an accurate sample of a disease occurring in the population as a whole. The number of patients studied in such special collections is small and the results are presented chiefly as arithmetic averages. None of the statistical collections with which I am familiar have sufficient material to permit of satisfactory age groupings; in practically none of this material are histological reports available, and therefore they, as well as the mortality statistics, are wholly valueless in forming a judgment as to the care of the individual case.

Dublin has approached the problem in a paper read at the Mohonk Conference² by preparing life tables of cancer from the registration area figures for 1910, 1922 and 1924. But such tables have the inherent errors mentioned above and treat the disease as an entity without reference to organs or types. Such material is useful for propaganda purposes to dramatize the situation, but lacks the specificity required to be of practical value.

The best analysis with which the writer is familiar is that of Professor Major Greenwood.³ In his short paper the author discusses with great shrewdness the actuarial difficulties which render special collections no true sample of the population, the errors which underlie the alleged duration of untreated cases, and other fallacies which unavoidably creep into the primary records which furnish our only material for study. Supplementary evidence is available in a report by Sir George Buchanan for the League of Nations. (III. Health, 1927, III, 17.) There the mean duration of cancer of the breast and cervix of Italian women is shown to be very much smaller than for

English women, and the report cautiously suggests that there may be racial differences in growth rate. This may be a statistician's explanation; but the physician who sees a large amount of Italian material will rather believe that the ignorance and superstition so evident in the Italian peasantry may be reflected in the short duration of neoplasms in the race because the disease is only recognized at a late stage, and after all we only have the patient's statement as to duration. The difference in operability for cancer of the breast in the educated classes as contrasted with the advanced lesions seen in the manual laboring people is a commonplace matter to every physician of large clinical experience.

CONCLUSIONS

1. Making cancer a notifiable disease would in time greatly increase our knowledge of the multifarious group of diseases now roughly grouped for statistical purposes under a single head of cancer.

2. It would stimulate the physician to early diagnosis, as he would be later checked up by someone else if he failed to diagnose the tumor promptly.

3. Such an official record would encourage the patient to make use of the best treatment and would do a good deal to inhibit the activities of the quack, who would be exposed to publicity through the premature death of his patient. This partial control of the patient's activities through the state or local boards of health is one of the most important collateral effects of such notification.

4. The compulsory registration of all cancer cases would be a check on the death certificates which are now frequently signed "heart disease" or "pneumonia" in deference to the family's wishes.

5. When such notification becomes fairly widespread, invaluable records of the rate of growth of tumors, and length of life of the patients (which are not synonymous) will be obtained. It is not too much to hope that within two decades it would be possible to have a still more complete record of the types of cancer which offer a reasonable chance of cure; in fact, microscopic slides from such patients, or a photomicrograph from such a slide would be a part of the death certificate. Only the larger hospitals now store microscopic slides from all their cancer cases in order to have a medico legal record as to the correctness of the diagnosis; but the development of county hospitals with more or less satisfactory laboratory services is rapidly going on and their records will ultimately be available.

The first step that must be made is to have the disease notifiable. We will then be able to get at the present crying need, which is not of mortality records, but of the number of people who have cancer in a community and the length of time which they live after such a cancer is discovered. How can one decide whether an operation or X-ray or radium treatment is justifiable even from the purely palliative point of view if there exist no trustworthy figures as to the length of life in a similar group of cases wholly untreated? And yet every patient with cancer offers this and other problems.

What is the chance of cure by removal of the tumor? If cure is not possible, will a palliative operation really prolong life, and if so how much? Does either radium or X-ray offer a better palliation in case removal is impossible? Will a combination of the two be better than either alone?

Making cancer a notifiable disease will not answer many, much less all of these questions, but it will in time solve some of them, and if we may reasonably hope for complete notification records throughout the country twenty years from now, a beginning must be made immediately. Do we not still suffer from the disgrace of being a civilized nation with a "registration area"?

DISCUSSION

FREDERICK L. HOFFMAN, LL. D., F. A. P. H. A.

*Consulting Statistician, Prudential Insurance Company,
Newark, N. J.*

IN the light of many years' experience, I am absolutely convinced that the registration of cancer patients is feasible on the part of the local health authorities. The objections, raised in the light of local experience, which have proved a failure, do not in my judgment operate against the proposal. Such objections have always been raised against notification of other diseases, particularly typhoid fever, leprosy, and most of all, the venereal diseases. It will take time, of course, to build up a system of reasonably complete notification, but I am absolutely convinced that this is possible.

I am familiar with the unsatisfactory experience which has been had in Massachusetts. Dr. Lombard, Director, Division of Adult Hygiene, of the Massachusetts State Department of Health, writes me with reference to this matter, in part as follows:

This department feels that the reporting of cancer is not practicable at the present time. We attempted a cancer morbidity reporting area in the city of Newton with the idea of determining whether it was advisable to make cancer reportable for the state as a whole. This experiment was a failure, as only about one-third of the cancer in Newton was reported.

It would be expecting too much that a new movement in public health should be a success from the outset. The late Eugene R. Kelley, M.D., former State Commissioner of Health of Massachusetts, was firmly convinced that it was a practical possibility. It is all a question of intelligent statutory regulations and of sufficient force exercised on the part of the health departments with the coöperation of physicians to make the measure a reasonable success. But these are naturally reluctant to assume additional clerical burdens, and fail to realize that they are accountable to the community. Compulsion alone will insure success. I agree that voluntary coöperation is always a failure.

Dr. Lombard writes further to the effect that—

On three occasions we have questionnaired all the physicians in Massachusetts regarding the volume of cancer. About one-third of them replied, and from their answers we estimated that at any one time there are about twice as many cases as there are annual deaths.

I am satisfied that voluntary registration is a hopeless effort. The matter must be made a statutory requirement and derelict physicians must be held to account for their failure to obey the law.

Dr. Lombard also pointed out to me that an effort was made to obtain information by house-to-house surveys, and that five localities are at present being investigated in this manner, with other localities in prospect. But such an effort gives merely a cross-section on a given date and does not meet the real necessities of the situation. Not much of value has been forthcoming as the result of so-called sickness surveys just for the reason that they are merely cross-sections and do not present a continuous line of observations.

Cancer should be reportable because of the need for definite information as to the course followed in subsequent treatment. The real underlying reason for our present excessive cancer death rate and the increase in cancer mortality is due to the vast amount of superficial early treatment, responsible for delays which ultimately result in death. Until we take the cancer situation more seriously and remove it from the present-day apathy and indifference, no reduction in the rate by deliberate means and methods will be successful. Every suspicious tumor case should be promptly reported to the authorities, and every effort should be made to insure to the patient the best possible mode of treatment. That would be absolutely impossible without notification and I therefore sincerely trust that this Association will put itself behind a recommendation that cancer throughout the country be made a notifiable disease.

But this is merely the first step in the right direction. As a second step, there is the utmost urgency for a complete follow-up system, at least in all hospital cases. Cancer is a chronic disease which must be watched with the utmost care, even after operation. Countless persons fall victims to cancer because of post-operative neglect and indifference. Furthermore, there is the necessity of ascertaining a correct measure of operative results, and only collective aggregates on a large scale can give us figures useful for the purpose of public instruction.

Until the public has exact data showing the truly amazing results of early treatment in cancer cases and the ratio of survivals after a number of years, it will remain unconvinced about much of the present-day propaganda for early treatment. There is nothing else to go by than the assurance that early treatment affords a reasonable hope for a cure.

The methods in this respect which have been followed by the Ministry of Health of Great Britain, particularly in the admirable reports of Dr. Jane Lane-Claypon, are deserving of serious consideration. We need such statistics for this country for we have every reason for believing our American operative results and radiological results will prove equally encouraging, if not more so.

Mention may also be made of the encouraging statistics published in English by the Radiumhemmet of Stockholm on the great value of radium treatment. It is precisely such information that we are really most in need of for this country. In other words, in the light of my experience with cancer investigations, the first necessity at the present time toward a better solution of the problem of cancer control is the compulsory notification of cancer cases amplified by extended investigations into the post-treatment results whatever the method of treatment may be.

The Duties of the Nursing Staff in a Health Department Communicable Disease Service*

AGNES J. MARTIN, R. N., F. A. P. H. A.

Director Bureau of Nursing, Department of Health, Syracuse, N. Y.

BEFORE discussing the duties of a bureau of public health nursing staff to a communicable disease bureau, let us consider the aims of these two services. While the aims of a communicable disease bureau may vary in different communities, the following were named by the chief of this service in the Syracuse Health Department:

1. Disease prevention
2. Enforcement of legal requirements
3. Epidemiological studies and research
4. Health education
5. Coöperation with physicians

The aims of a public health nursing service are described by Dr. Tobey as follows:

Public health nursing has as its object the saving of life, the upbuilding of family health, and the promotion of community sanitation and hygiene; it deals with individuals and families in its efforts to restore the sick to health, to find and correct physical impairments, and to teach the practice of healthful living and the establishment of hygienic habits.¹

Public health workers will see much in common in these aims, and the extent of service is limited only by the number of nurses available and the amount of contagion in the community.

The first means of measuring even a minimum of what might be expected in both services is given by the *Appraisal Form* of the American Public Health Association. The score is based on the following points: reporting, case investigation and recording, disease control, visits to cases, diagnostic service, hospitalization and immunization.

At first thought, it would appear that a nursing service had little to do with reporting of communicable diseases, but if the suspicious conditions reported by the nurse and verified by a physician are recorded, it will be found that she plays an important part. This was

* Read before the Public Health Nursing Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

evidenced by our own experience in an epidemic of measles which extended over 3 years—1926–1928. During that period 8,421 cases were reported, of which 2,187 or 26 per cent were reported by public health nurses, 23 per cent by those of the Department of Health.

In case investigation and recording, the public health nurse is the ideal worker, as the investigation furnishes the observation necessary for adequate quarantine, securing laboratory specimens, advice on hospitalization and immunizations, and a basis for the needed number of follow-up visits. The keeping of spot maps and chronological charts belongs to the communicable disease bureau. They are of great value, however, to the nursing bureau in creating interest and renewed effort in a danger zone.

Perhaps the most important factor in the success of a nursing service is the type of nurse employed. The first study made by this section of the American Public Health Association was on qualifications for public health nursing positions.² The requirements suggested were progressive in the time element, so are still valuable. Beside the qualifications required for any public health nurse, the moral and social qualities—honesty, faithfulness and dependability—are greatly to be desired. Health departments usually are not free to search the country for this type of worker, frequently being limited by civil service to their particular communities. Their staffs are likely to have some nurses, both old in training and in years, appointed before standards were considered important. Many of these have grown professionally through valuable experience and personal development, while others have plodded along satisfied with the status quo. It therefore becomes the duty of the department or bureau to carry on a continuous educational program on the newer methods of treatment and control of communicable diseases. There is no field in public health where "new occasions teach new duties, time makes ancient good uncouth."

What are some of the important things the public health nurse should know?

1. The nurse should know how to teach personal and home hygiene.

The community that furnishes instruction in personal and home hygiene is building its strongest defense against communicable diseases. Diet, rest, exercise, cleanliness, good habits of eating, sleeping and working, care of food, sanitation and ventilation of the home, furnish subjects for home visits and group instruction; but to practice routinely washing the hands before and after handling food, and after using the toilet; to avoid the common drinking cup or towel; to cover

the mouth in coughing or sneezing; is another matter. Thus to improve living conditions requires the utmost tact, patience and perseverance of the worker. It is too obvious to suggest that the nurse herself should be the exponent of this teaching, also that she protect herself through annual physical examinations and such immunizations as the service demands.

2. The nurse should be familiar with the Sanitary Code of the state and city.

There is considerable variation in the codes of various states and even some in various communities of the same state. These, however, may not be less stringent than that of the state department of health. A glimpse at the variations noted in the chapter on "Control of Communicable Diseases," in *Public Health Bulletin 164*, is most convincing on this point.³

3. The nurse should know the symptoms, periods of incubation and isolation, and approved methods of treatment of all common communicable diseases.

Knowledge of symptoms is important as nurses calling in the home on other errands are frequently the first consulted on conditions appearing suspicious. A card diagram giving such data as period of quarantine for patient and non-immunes, as well as other contacts in all of the common contagions, is provided by many states and serves as a helpful reminder.

Some might take exception to the suggestion that the nurse should be informed on approved methods of treatment. The inference that from such knowledge the nurse might proceed to advise treatment and thus invade the province of the physician is of course obvious. Since a large number of families unfortunately never call a doctor, it is very much of a question whether medical advice by the nurse is not justified. Superstitions and unscientific home remedies are all too common and must be combated by urging the acceptance of modern scientific methods.

4. The nurse should be familiar with the nature of the various infectious diseases and their mode of transmission.

This information is indispensable for teaching methods of control, since most diseases are transmitted through personal contact, direct or indirect. The nurse must know how they may be transferred through contact, food, insects, and inoculation.

5. Above all, the nurse should know methods of control through:

Recognition and report
Isolation of patient
Quarantine

Disinfection
Immunization

Recognition and Report—This requirement again emphasizes the importance of recognizing, especially, early symptoms. New York State puts the responsibility of reporting on the head of a private household or the person in charge of any institution, school, hotel, boarding house, etc. The physician, if present, bears the responsibility for instructing the family in precautions until a representative of the local health department calls. Many of the larger cities employ a diagnostician to verify major and rare contagions, after which the supervision is passed on to the nurse. When an epidemiological card is used it affords an easy and natural means of entrance into the home, and of securing helpful data on source of infection, contacts exposed, and possibilities of quarantine arrangements. When accurately obtained, these data serve as the basis for scientific studies which may add to the knowledge of disease and influence policies for its better control.

Isolation—In the case of a large family, crowded conditions, institutions, hotel, or boarding house, isolation is secured only through hospitalization. This is obtained in coöperation with the family physician or through action of the health officer. The sanitary code usually provides the necessary legal authority to enforce hospitalization if such facilities are available. It is interesting to note from the Report of the Committee on the Relation of Health Departments and Hospitals that health departments are utilizing general hospitals in many communities, the city paying for indigent cases on a per diem basis.⁵ However, there will always be instances in every community needing care where no hospital facilities are available, in which case health departments should utilize the visiting nurse. From a review of a number of annual reports of visiting nurse services, it would seem that this custom is increasing; one report showed 14 per cent of all calls made were on communicable diseases. *Public Health Bulletin* 164 states that in 1924 many cities did not advise concurrent disinfection except where visiting nurses were permitted to give bedside care.⁶

It is the duty of the official nurse to teach the mother, or other adult assuming responsibility for the care of the patient, the technic involved. The demonstration method is preferred, Pillsbury pointing out that any prophylactic technic to be successfully carried out must (1) appeal to reason, (2) be simple, (3) be adaptable, (4) be economical of time and money, (5) be understood in order for it to be practiced effectively and taught.⁷

Quarantine—The tendency today is to make quarantine more lenient, especially as it affects contacts. New York's code was markedly changed in this direction last July. If the understanding and co-

operation of the public are secured, it will lessen the hardships imposed. The American Public Health Association *Appraisal Form* gives a minimum standard of home visits believed necessary for each disease during the period of quarantine.* The public health nurse makes the ideal quarantine visitor. Her example in technic cannot fail to make an impression on the mother, especially when explained in simple and readily understood terms. When quarantine is broken her understanding of housekeeping, added to her technical knowledge, helps to make individual adjustments more readily than is possible for one without this training.

Disinfection—In teaching disinfection, it is important to know the location of the disease germs, and when and how to destroy them. Most germs are found in the discharges from the body. The daily care of this material as it is discharged is called concurrent disinfection, and instruction for its safe disposal must be very definite as to methods.

For the final or terminal disinfection, instructions are given for the clean-up of the patient and quarters. Most nurses can advise on the bath and shampoo but when it comes to the patient's room they frequently still think of fumigation when all that is required is thorough scrubbing with soap and water, plenty of air and sunlight. The length of time of exposure to sun and air depends on the strength of the sun's rays. Freezing should not be depended upon to destroy germs.

Immunization—Here especially is it necessary for the public health nurse to know the newest practices regarding control and treatment. She does not, of course, advise on treatment in the presence of disease if a doctor is in attendance but it is important that she know of the various vaccines, serums and toxins to answer questions intelligently, and urge immunization.

There is just one other thing that the writer would urge for an adequate alliance between a nursing bureau and all other bureaus requiring nursing services, and that is the adoption of the generalized form of nursing. True, the nurse under this system may lack highly specialized technic, but her broader understanding more than offsets this handicap and she usually enjoys a greater confidence of the people of her district. Furthermore, the ability to swing a large group of experienced workers into the contagious field in the face of an epidemic, or mobilize this group for any other special need, is no minor argument.

Beside all this, the nurse functioning in a generalized plan has an opportunity to arrange for the maintenance of the health of a family without the confusion which is apt to arise when two or more advisers

consult with the mother. Trying to meet all the health and social problems arising in a family is a challenge to the alert nurse, and offers an opportunity to do constructive work of the highest order.

The same set of nurses are on duty at all clinics and health conferences, and follow the children through the school health program. They inspect and supervise child boarding homes. With their knowledge of a family's health and social needs well defined, the generalized nurse does less transferring of information, with less opportunity for confusion in the home.

SUMMARY

The responsibilities and opportunities of a communicable disease nursing service in a health department should be—

1. Teaching personal and home hygiene to the family as a unit.
2. Recognition and reporting of probable communicable disease.
3. Establishment, supervision, and release of quarantine.
4. Propagandizing of accepted immunization procedure.
5. Securing adequate nursing care.

Malaria

DURING the summer and early fall of 1929, malaria appeared to be more than usually prevalent in many districts from which it had largely disappeared. In parts of Missouri, where malaria has been practically unknown for ten to fifteen years, quite a number of cases have been observed, and the correctness of the diagnosis proved by microscopical examination.

In the *Journal of the American Medical Association* for October 26, 1929, it is stated that focuses of malaria have developed in a number of the central counties of Illinois, and a warning is sounded of an increase for next year. Some fifteen counties in central Illinois have reported cases. It is well known that malaria was formerly quite common in Illinois, but the incidence of the disease had decreased greatly. The interesting feature of these reports is the explanation given by the State Department of Health, which attributes the notable increase to the use of automobiles and the contact with the South through such traffic. This explanation may be true, but we hope that a careful investigation will be made as to whether or not it is correct.

The Administrative Significance of Proposed Changes in Standard Methods of Water Analysis*

JOHN F. NORTON, PH. D., F. A. P. H. A.

Department of Health, Detroit, Mich.

THE primary purpose of *Standard Methods for the Examination of Water and Sewage* is to establish uniform methods for use in public health and other laboratories for testing the potability of water supplies; it also endeavors to furnish laboratory procedures for the control of water purification processes. I hope that a further result has been the stimulation of laboratory workers to improve on the published methods and to devise new and better ones. The standard procedures have also been used for the sanitary examination of swimming pools; for investigations of stream, lake and harbor pollution; and for the analysis of sewages and sewage effluents. Certain of the methods for mineral analysis of water have also been included.

The last (sixth) edition was prepared under the supervision of committees of the Laboratory Section of the American Public Health Association, the American Water Works Association and the American Chemical Society. While the methods recommended are generally regarded as the "Standard Procedures," it is a fact that many laboratories deviate from them to a greater or less degree. In some instances antiquated procedures have been retained; in others, newer ones have been adopted; but in many instances the deviation from Standard Methods has been because of some special local conditions. It is therefore wise to make a periodic survey of the recommended procedures. I shall try to present to you, as briefly as possible, the changes that have been suggested for consideration in preparing the seventh edition, and shall dwell particularly on those that have a direct bearing on administrative control.

It cannot be emphasized too strongly that what I have to say is tentative in character. The changes that will be discussed have not been adopted, and at least a year will elapse before final action on

* Presented at a Joint Session of the Public Health Engineering and Laboratory Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

any of these proposals can be taken by this Association. There is, therefore, time for further discussion and criticism.

Chemical Methods—No changes are contemplated in the methods intended for sanitary chemical examination. In connection with the mineral analyses, however, numerous suggestions have been made. There appears to be rather general agreement that the "drop-ratio" method for determining the hydrogen ion concentration should be abandoned. It is too crude to be recognized as a standard procedure. Furthermore, there is no necessity for such a method since there are now available excellently prepared buffer standards. In addition to the hydrogen electrode potentiometer method the quinhydrone cell is now available for rapid and fairly accurate work. In the preparation of laboratory mediums, colorimetric methods, if carried out with carefully prepared buffer standards, will probably continue to take precedence.

It has been suggested that a method for the determination of phosphates be included and that a simpler quantitative test for manganese be tried. The method for the quantitative estimation of hydrogen sulphide must also be revised. The present edition gives methods for the separation of sodium and potassium. There is some doubt as to the advisability of including these procedures. Since a complete mineral analysis of a water is somewhat laborious, those interested in water softening processes have devised more rapid although less accurate methods for obtaining the information essential for these processes. It seems that some of these rapid methods might well be recognized as standard procedures. The same is true of those for the detection of chemicals used in water purification, such as alum, ferrous sulphate, soda ash, lime and calcium hypochlorite. The methods would include only those that are recognized as both accurate and practical. A method for the estimation of iodides has also been suggested as of possible value.

Some criticism has been made of the present methods for determining the turbidity of waters. Such a determination is of great value in connection with water filtration. Baylis has suggested that all turbidity measurements be referred to the values obtained with the Jackson turbidimeter.

Sewage Examination—The temperature for drying of solids is now given as 103° C. In water examination, the standard temperature is 180° C. This discrepancy should be removed. Probably 180° C. should be adopted for both materials. The inclusion of methods for the determination of total, fixed and volatile sulphides has been suggested. It is not quite clear whether the analytical procedures

have been sufficiently standardized to include them at this time. A quantitative procedure for the determination of phenols would seem to be an excellent addition to the present methods. There is no doubt that the presence of these substances in water supplies must be taken into account. Several modifications of the method of Gibbs have been investigated, and I believe that agreement on at least a provisional procedure could be obtained. A very desirable but difficult determination is that of settleable solids in sewages. The standardization of some method such as that devised by Imhoff, or some modification of this, might well be recommended. At present there is little uniformity in such determinations.

Microscopic Methods—The present microscopic methods are inadequate. This section of the book must be revised and enlarged. It is well known that higher organisms are of great importance in reservoirs and in connection with the self-purification of streams. A committee has been asked to make revisions but in addition to those on this committee, it is highly desirable that others interested should offer criticisms and suggestions. There is nothing definite to present at present.

Bacteriological Methods—More discussion has centered about these procedures than other sections of "Standard Methods." The referee for the Committee on Standard Methods has prepared a careful report. I shall summarize his proposed changes, omitting, however, some few which concern only minor details. The present method for sterilization of glassware calls for a "temperature of not less than 160° C. for not less than one hour." It is believed by some that this temperature and time, when carefully adhered to, give satisfactory results. Others maintain that the leeway is too small and that a higher temperature, such as 170° C., should be specified. Where the temperature in the oven is known to be uniform throughout, 160° C. might be allowed.

It has been recommended that the instructions for the preparation of nutrient agar should omit the directions to "cool to 45° C. in a cold water bath then warm to 65° C. in the warm bath without stirring." As far as I am aware, this is almost never adhered to and there is little reason for doing it.

Trouble has been encountered in the preparation of Endo medium. It is believed, however, that the directions as given will produce satisfactory results provided certified fuchsin and chemically pure anhydrous sodium sulphite are used. However, an alternative procedure might be considered.

Attention should be called to the water used for dilution of samples

to be plated. Under no conditions is it desirable to use distilled water. No definite suggestions have been offered for a synthetic dilution water, but it is hoped that some will be forthcoming.

Some bacteriologists feel that a simple stain rather than that of Gram should be used for the identification of *B. coli*. This would necessitate a change in the definition now used for the coli-aerogenes group. I have been able to find very little support for this suggestion.

One important item refers to the necessity of obtaining isolated colonies on plates containing either Endo or eosin-methylene-blue medium. The characteristic reaction often fails to appear unless such colonies are obtained, and organisms of the coli-aerogenes group are consequently not reported as required in the partially confirmed and completed tests. Since many laboratories doing routine work do not carry the tests through, it is important to make the partially confirmed test as accurate as feasible. If this suggestion is approved, it will result in an increased number of *B. coli* being reported.

The present edition suggests tests for differentiation of fecal from non-fecal members of the coli-aerogenes group. This section was included because the committees felt that such procedures might be of value to workers in the smaller laboratories who do not have many books available. It was also thought that further work would be stimulated by giving some prominence to the methods. During the past two years, several new mediums have been devised for the differentiation of members of the group, some of which will be discussed later. The section has been criticised because it is not recognized as being included in the standard procedures and the referee acting for the Committee on Standard Methods has recommended its elimination. His recommendation has not been favorably received.

B. coli may be completely killed in a lactose broth medium at the end of 48 hours if the acidity of the medium attains a pH of about 4.2. Accordingly, if the standard procedures are carefully followed, many tubes which contain gas at the end of 48 hours do not give the confirmatory test for *B. coli*. It is therefore recommended that all tubes showing gas at the end of 24 hours should be tested for the presence of the coli-aerogenes group by transferring material to an Endo or eosin-methylene-blue plate. This suggestion was made in the present procedure but was not consistently followed. Another method for accomplishing the same result as far as survival of this group is concerned, would be to add buffer salts to the standard lactose broth. Preliminary work by Butterfield has shown that phosphates might be used for this purpose.

The most important suggestion in connection with the determina-

tion of the coli-aerogenes group organisms has been in connection with the use of a brilliant green bile medium. According to the work of Jordan, Dunham and their collaborators, this medium should contain 2 per cent of bile, with brilliant green in amounts sufficient to give a concentration of 1/75,000. The reaction after sterilization should be between pH 7.1 and 7.4. A very large amount of material has accumulated which indicates the value of this medium both for a primary inoculation in parallel with the standard lactose broth, and as a secondary medium for the partially confirmed test. Opinions on the use of this medium are, however, not unanimous, but it seems that certain definite suggestions could be formulated so as to allow the medium to be used in a way satisfactory to most laboratory workers.

The present edition of *Standard Methods of Water Analysis* suggests one method for reporting the results for the coli-aerogenes group on the basis of numbers per c.c. or per 100 c.c. Much difference of opinion exists as to the best form of calculation for these results. On the one hand there are some who advocate a simple reporting on the basis of number of tubes confirmed for this group. Others advocate a more complex and, possibly, a more mathematically correct procedure. The matter will have to be straightened out through frank discussion.

It has been suggested that the method for preparation of broth mediums be so written that after the addition of the water sample, the medium will be of a uniform composition. This would necessitate the preparation of a more concentrated medium where 10 c.c. portions are to be used, and the use of a definite amount of this medium in each tube. This is a practical suggestion.

The large and well equipped laboratory with experienced workers does not need as definite directions as may be required by the small laboratory and the relatively inexperienced worker. It has, therefore, been suggested that for the examination of finished waters a definite number of portions of given size be used in conformity with the requirements of the U. S. Public Health Service. The following set-up of tubes might be recommended—five 10 c.c., one 1 c.c., and one 0.1 c.c. portions.

Standard Methods makes a very definite recommendation in regard to the lens used for counting bacteria. As a matter of fact, this recommendation is rather generally disregarded. Either no lens is used, or some method of lighting and magnification devised in the laboratory, or some commercial apparatus may be at hand. Where a large number of plates are counted each day, the hand lens is unsatisfactory. Agreement should be reached on this point.

During the past two years a number of mediums have been devised for counting coli-aerogenes group organisms by the use of direct plating methods. It is claimed that these will not only give a direct count, but will differentiate fecal from non-fecal strains. While it is recognized that such mediums would be of great value in water examination, their use has not been extended over a wide enough range of laboratory workers to warrant their inclusion in Standard Methods at present.

The Committee on Standard Methods of the Laboratory Section has recommended the inclusion in the next edition, as a supplement, of the report of the "Advisory Committee on Official Water Standards," appointed by the Surgeon General of the U. S. Public Health Service. Their recommendations are known to be the generally accepted standards in this country, and it is felt that it would greatly add to the value of the volume if they could be included. Permission from the Surgeon General is being requested in order to carry out this recommendation.

Swimming Pools—With the development of adequate methods for the purification of swimming pool water it has been necessary for the laboratory to examine specimens at frequent intervals as a control on the operating procedures. It is recommended that methods for the examination of water be used also for the examination of swimming pools with the understanding that the portions used for analysis be varied according to the extent of purification. No attempt would be made to suggest standards for interpretation of the results, since they are not considered pertinent to the other laboratory procedures described. Methods for the examination of swimming pools for respiratory organisms must await further work.

SUMMARY

I have attempted to enumerate the most important suggestions that have been made for changes in the present edition of *Standard Methods for the Examination of Water and Sewage*. These changes have for their object the inclusion of additional methods for the Chemical Analysis of Water and Sewage so as to increase the usefulness of the book. Such proposed additions include rapid methods for boiler water analysis, the determination of phenols in water and sewage and the analysis of chemicals used in water purification.

The proposed changes in the bacteriologic methods are made with the object of simplifying the control of plant operation by laboratory methods, including the recognition of the fact that such methods must be distinct from those used for the final analysis of a finished water.

The plant manager at present is inclined to use methods other than those regarded as standard, because they have not proved practical from his standpoint.

The proposed changes in the bacteriologic methods will tend to increase the number of positive presumptive tests partially confirmed and completed. These results can be accomplished by more careful attention to some of the details in the procedures.

Milbank Memorial Fund Demonstrations

MARKED reductions in deaths from preventable causes have occurred in demonstration communities where the Milbank Memorial Fund is spending \$2,000,000 in public health promotion.

The 1928 death rate from tuberculosis in one of the communities, rural Cattaraugus County in New York State, is reported as the lowest on record in that county—39.1 per 100,000 population. This is the fourth successive year in which the death rate from this disease has been below any annual rate prior to the inauguration of the demonstrations.

Over the past four years, fewer deaths from diphtheria have been reported from Syracuse, another of the demonstration communities, than at any time during the recorded history of the disease in that city, which reaches back over the past 29 years.

New York Health Demonstrations were begun in 1923, the Fund having made appropriations to supplement the resources of public and private health agencies in three demonstration localities in New York State, in order to help them develop locally effective and adequate public health administrative machinery. In addition to the rural Cattaraugus County and the urban Syracuse demonstrations, a third is in progress in the metropolitan Bellevue-Yorkville district of New York City.

It is estimated that a reduction of over 40 per cent in diphtheria cases among children of school age resulted from the prevention campaign carried on in Syracuse. A reduction of 39 per cent in a similar group is attributed to the immunization campaign in Cattaraugus County. In the latter demonstration center, over 60 per cent of the population in the ages 6 to 11 have been given the preventive treatments for diphtheria.

In the Bellevue-Yorkville Health Demonstration in New York City, progress has been notable in the administration of toxin-antitoxin to the children of the district; in the development of a program of health education and of a tuberculosis consultation service; and in forwarding a campaign for regular and more intensive physical examination of school children.

While in its twenty-four years of activity the Fund has made substantial grants for the advancement of social welfare and general education and, to a lesser degree, for charitable relief, considerably over half of its income has been devoted to the promotion of public or community health—to aid in the acquisition and application of knowledge and methods for improving the health and vitality of people. The Fund has coöperated in many such enterprises other than the New York Health Demonstrations—some of them in remote parts of the world, but the majority in the United States, and particularly in the City and State of New York.

Annual Health Department Reports*

THE committee has given its chief consideration this year to the kind and form of tables which should be presented in the annual health department report. These tables are mainly related to vital statistics and communicable diseases, although certain other tables are believed to be desirable. It is believed by the committee that somewhat more detailed historical statistical tables should be presented once in 5 years than is necessary every year, and a subsequent report will suggest quinquennial tables for this purpose.

The health department report is usually prepared for the health officer, the press, city officials, civic leaders, schools, libraries, and for exchange with other agencies. The report serves as a city record as well as for the health officer's purpose of "taking account of stock." The statistical information contained in the report is the fuel of the epidemiologist. The value of the report depends in no small degree upon the early availability of this material for research work and program planning.

Every annual report, regardless of the size of the community, should contain tables showing the births, deaths, stillbirths and marriages, together with the population for the past 10 years. These might also include infant deaths and infant mortality rates.

TABLE I
POPULATION, BIRTHS, DEATHS, MARRIAGES, WITH RATES

Year	Population Est. July 1	Births (still- births excepted)		Deaths (still- births excepted)		Stillbirths		Marriages	
		Total	Per 1,000 Population	Total	Per 1,000 Population	Total	Per 1,000 Births	Total	Per 1,000 Population
1920									
1921									
1922									
1923									
1924									
1925									
1926									
1927									
1928									
1929									

For quinquennial reports, which may be prepared in greater detail

* Report of Sub-Committee on Annual Health Department Reports of the Committee on Administrative Practice of the American Public Health Association, May 28, approved December 5, 1929.

and with more comparative data, it is suggested that the above table be modified to give data for each census year, for as long a period as such data are available, preceding the quinquennial period of the report. It is desirable that all statistical tables be accompanied by sufficient descriptive text to render the data clear and interesting.

Births should be classified, as in Table II, and it is suggested that a legitimacy column may also be added.

TABLE II

BIRTHS, BY SEASON, SEX, COLOR, AND KIND OF OBSTETRICAL CARE

Months	Males	Females	Total	Colored Children Included in Preceding		
				Males	Females	Total
January						
February						
March						
April						
May						
June						
July						
August						
September						
October						
November						
December						

Obstetrical Care	Number	Per cent
Hospital		
Home, private		
Home, clinic		
Midwife		
Total		

If it is desired to correlate the kind of obstetrical care with parentage of mother, the following is suggested:

Obstetrical Care	Color and Nativity				Parentage		
	Native White	Foreign Born White	Negro	English	Irish	Italian	Portuguese, etc.
Hospital							
Home, private							
Home, clinic							
Midwife							
Total							

Table III classifies deaths by sex, cause and age. This is the largest table in the report and may be used for all communities of over 25,000 population. If more than 10 per cent of the population are colored, another table might be made for this group.

Deaths under 1 year should be classified by cause and age. Season and color may be likewise included if desired.

TABLE V

DEATHS UNDER 1 YEAR BY CAUSE AND AGE, 19—

No.	Cause	Under 1 Day	1 Day and under 2 Days	2 Days and under 3 Days	3 Days and under 4 Days	4 Days and under 5 Days	5 Days and under 6 Days	6 Days and under 7 Days	7 Days and under 8 Days
7 9 10	Measles Whooping Cough Diphtheria (etc.)								
Totals									

No.	Cause	1 Week and under 2 Weeks	2 Weeks and under 3 Weeks	3 Weeks and under 1 Month	1 Month and under 2 Months	2 Months and under 3 Months	3 Months and under 6 Months	6 Months and under 9 Months	9 Months and under 1 Year	Total under 1 Year
7 9 10	Measles Whooping Cough Diphtheria (etc.)			1	2	2 1	8	6 9	10 7	16 29 1
Totals										

A table showing deaths under 1 year of age according to the nativity of the mother may be used for larger cities, and should be included in quinquennial reports. A table showing puerperal deaths by cause and obstetrical care, with the age and mother's nativity, is desirable although not always essential.

For the tabulation of cases and deaths of reportable diseases, the committee suggests the use of the table adopted by New York State.

A table should be included to indicate the hospitalization of communicable diseases and Table VII carries suggestions.

The final table should be a classified financial statement for the year of the report. Comparisons with the previous year may be used

TABLE VI

REPORTABLE DISEASES; CASES AND DEATHS BY MONTHS, AND ANNUAL CASE, DEATH, AND FATALITY RATES, 19—

Int. List Nos. (Third Revision, 1920)	Causes of Sickness and Death (Listed in order of New York State Sanitary Code)	Total					Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.		Oct.		Nov.		Dec.

C. Venereal Diseases.....	6,400	2,500	8,900	8.9
4. Child Hygiene				
A. Maternity, Infant and Preschool Hygiene..	9,000	1,500	10,500	10.5
B. School Hygiene.....	20,500	2,000	22,500	22.5

(In like manner, list other activities: Sanitation, Food and Milk, Laboratory, Public Health Nursing, etc.)

* Figures from Summary Budget Revised Plan of Health Organization for City of 100,000 Population. *Community Health Organization*, A. P. H. A., 1927.

A supplementary statement of official expenses for public health not included in the health department budget, such as vital statistics or hospitalization, should be added. Activities listed which are not strictly public health measures should be starred.

In addition to the above tables, summary tables of inspection, nursing, laboratory, medical and clinic activities should be presented with appropriate descriptive text. Subsequent reports of the committee will outline such tables in greater detail.

It is recognized that the publication of statistical tables is expensive, and for this reason some health departments, including Providence, R. I., have utilized zinc cuts from typewritten proofs, with resulting material savings.*

SUGGESTED CHARTS FOR ANNUAL OR QUINQUENNIAL REPORTS

1. Organization chart of department
2. Trend of population
3. Trend of expenditures
4. Birth rate
5. Infant mortality rate
6. Death rate (all causes)
7. Death rates from the 5 or 10 locally principal causes of death

PHYSICAL MAKE-UP

Size—The size should be convenient for reading and filing, preferably 6" x 9", allowing about 3¾" x 6½" for the printed page.

Paper—Good paper, adapted to the character of the report, preferably without a glossy finish, is recommended. Coated paper is distressing and is used only because it takes half tones easily. If this must be used, dull coated paper is preferable, but if there are no half tones, coated paper should not be used.

Type—The choice of type is obviously an important question, and in general it is well to stick to a few standard faces on which there is no possibility of going wrong. A reliable printer is highly desirable. Legibility is dependent principally on the length of line in relation to type used and the space between the lines. Ten point should be set not wider than 4 inches; and 8 point not wider than 3 inches. Ten point type, if properly used, is sufficiently large for effectiveness in city reports.

Appraisal Form—Several health officers have effectively introduced into their reports the *Appraisal Form* schedule of the Committee on Administrative Practice of the American Public Health Association. Even if a rating is not made on the *Appraisal Form*, the questionnaire portion of the publication is useful as an outline of data to be included in a report.

Literary Style—The text should be clear and concise, reflecting proper attention to grammar, sentence structure, and diction.

Balanced Content—The material should show a complete picture, and each activity should occupy space in proportion to its relative importance.

* From a typewritten copy of the table, a line cut one-half size is made, saving in labor and proof reading. Care must be taken to use a good, clean ribbon and to have the typewriter itself well cleaned. Choice of type is important as the reduction is the same in thickness of lines as in size of letters. Tables III, IV, V, and VI may be made by this method.

Seasonal and Age Studies of Poliomyelitis and What They Suggest*

W. LLOYD AYCOCK

Harvard Medical School, Boston, Mass., and the Research Laboratory of the Vermont Department of Health, Burlington, Vt.

A PREVIOUS study of the age distribution of poliomyelitis in comparison with that of measles and diphtheria,¹ in which diseases the phenomena responsible for age distribution can be measured by direct observation or test, indicated that the virus of poliomyelitis is widespread and that it sets up a widespread immunity to the disease. It was concluded that the incidence of the disease is not in reality a measure of the extent of the distribution of its virus but is limited to a great extent by existing immunity which must have come from previous exposure to the virus.

This observation raised the question as to what determines the result of initial exposure to the virus—the frequency with which it causes an actual attack of the disease or produces (or at least begins) a sub-clinical immunization which may or may not be reinforced by subsequent exposures. While this study suggested that the frequency of the occurrence of the disease was not a function of facility of contact, it gave no indication as to whether immunization or disease is the result of some quality of the virus in respect to dose or virulence, or of some quality of resistance on the part of the host.

In a second study² evidence was presented which indicated that the extent of the distribution of the virus is the same in warmer climates, where the incidence of the clinical disease is less, as in cooler climates where the disease has its greatest incidence. An analysis of variation in incidence together with seasonal fluctuation in cooler and warmer climates indicated that the climatic variations could hardly be attributed to corresponding variations in the facility with which the virus is transmitted or in its virulence. It was shown, however, that the seasonal fluctuation, as well as the incidence, correlated with the extent of seasonal fluctuations in climate but not with climate itself. In other words, poliomyelitis is a disease of warmer seasons

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

but of cooler climates, its incidence, generally speaking, varying directly with the magnitude of the change from the colder to the warmer season of the year, but not with the warmth of the climate itself.

It is known that numerous bodily functions undergo corresponding seasonal fluctuations doubtless in the nature of normal adjustments of the body to a varying environment. It was pointed out that some of these seasonal fluctuations in physiologic functions bear a direct relation to the occurrence of certain noninfectious diseases; to susceptibility to certain chemical compounds, the toxicity of which depends on the rate at which they are broken down in the body into their poisonous constituents, and which rate varies with the seasonal activity of certain bodily functions; and that susceptibility to certain infections is influenced by physiologic factors which undoubtedly undergo similar seasonal variations.

This study led to the opinion that resistance to poliomyelitis in the first instance may lie in a balance between some as yet undetermined physiologic processes which undergo seasonal fluctuations and vary in different climates by way of adjustment of the body to different or changing environment. Failure of the seasonal adjustment would result in a deficiency or discrepancy which would be greater in cooler climates where fluctuation in the seasons is greatest, and least in warmer climates where fluctuation is least. It was pointed out that certain observations regarding the type of individual in whom the disease seems to occur with greater frequency than in the average, a type suggesting some physiologic imbalance, tended to support this hypothesis.

In order to define more clearly this kind of resistance to disease as a matter of convenience; to distinguish it from immunity (i.e., resistance which arises as a reaction product between the infecting agent and the host) as well as to call attention more sharply to a form of resistance which since the advent of the germ theory of disease has, I believe, been neglected; I have suggested that it be designated by the term "autarcesis," which may be defined as the power to resist infection which resides within the individual's normal physiologic functions and which does not require the provocation of the infectious agent for its production.

From this conception of the epidemiology of poliomyelitis some idea of the nature of the virus reservoir of the disease can be formed which is in accord with other observations which need not be enumerated here. Furthermore, from an analysis of some of the general features of the disease some notion may be gained of the probable behavior of this virus reservoir which cannot be ascertained with the

limited facilities available for the actual detection of the virus. This question has long been before students. Where does the virus maintain itself in areas where, and at times when, the disease is highly prevalent, in interepidemic periods, in areas where the incidence of the disease gives no hint of its presence other than the occurrence of sporadic cases, or more or less widely spaced outbreaks, and in the winter and spring when its presence is indicated only by occasional cases?

I have previously pointed out that we need not look for any condition peculiar to any one area which would serve as a virus reservoir. This is obvious from the simple fact that no part of the inhabited world is entirely free of the disease, and is further emphasized by the fact that regardless of the incidence its age distribution indicates an equally widespread immunization and, hence, an equally widespread distribution of the virus in all parts of the world from which figures are available.*

Since the widespread process of immunization which has been referred to apparently takes place with a rapidity corresponding to concentration of population, as is the case with such well known contact diseases as measles and diphtheria, it seems reasonably certain that the mode of dissemination of the virus of poliomyelitis is likewise by direct person to person contact. No evidence has been found that the virus reservoir may lie largely in chronic carriers. No instances are known where one individual seems to have been responsible for the transmission of the virus to any number of others over a considerable length of time. It would rather appear that the virus reservoir is in reality the upper respiratory passage of large numbers of individuals who, so far as the evidence indicates, harbor the virus for a relatively short time during which by far the largest proportion acquire an immunity without showing obvious signs of the disease. It is still a question as to what proportion of individuals may show mild symptoms following an infestation, known as abortive poliomyelitis, or what proportion of them become immunized without any noticeable reaction to the virus.

There is no positive indication that the virus of poliomyelitis can actually be transmitted with greater facility at one season than another. In fact, we now see that increased opportunities for contact due to closer aggregation of the population in winter, long supposed to be responsible for the seasonal prevalence of the common contact diseases, can hardly be the true explanation. If this were true one

* There is only one probable instance of the introduction of the virus into a virgin population. On the island of Nauru, in 1910, the disease reached a very high incidence and apparently occurred with equal frequency at all ages.

seasonal curve should be common to all these diseases; and the seasonal curve of none of the contact diseases has been shown to coincide with variations in the aggregation of population. For example, the seasonal increase in diphtheria long supposed to follow the opening of schools, actually is on the upward trend before the opening of schools. Finally, it remains to be shown that the magnitude of seasonal variation in "opportunities for contact" even begins to approach the seasonal variations in the prevalence of these diseases.

In view of previous studies mentioned, which suggest an autarcetic factor which varies with season, one can at least raise the question whether an initial infestation with the virus of the disease produces the clinical disease or an immunity, largely according to the season of the year when infestation takes place. In this connection it may be stated that while mild cases are not infrequently detected, solely by reason of their proximity to frank cases, we have not found evidence that any considerable number of such mild febrile attacks, which might be regarded as abortive poliomyelitis, occur as an undercurrent of summer outbreaks of the frank disease. However, the evidence in regard to the age distribution indicates that the large majority of the population acquires an immunity in the course of a life time. This would imply that infestation with the virus is correspondingly widespread, from which it may be inferred that, on the average, approximately 1 out of 50 of the population receives an initial exposure each year, or 1 out of 600 of the population in any given month.

In the hypothetical case of a city of 100,000, shown in Figure I, approximately 166 initial exposures would occur each month. It might well be supposed that the virus of poliomyelitis might be spreading with equal rapidity throughout the year, but that during the winter and spring months by far the vast majority of initial exposures would produce no symptoms, or some mild reaction not recognized as poliomyelitis; while as the summer season arrived, on account of a general diminution in autarcesis, a larger and larger proportion of infestations would result in attacks of the recognizable disease rather than in a mild reaction which would pass unnoticed.

In the hypothetical case illustrated, it will be seen that an epidemic of an intensity which is seldom exceeded (2 cases per 1,000 population) could occur in the summer season without any actual increase in the rate of dissemination of the virus. It is not to be understood that this moving virus reservoir is necessarily present in every locality all the while. Local epidemics may follow its introduction or presence during the season of anautarcesis (summer and fall), or if a particular locality has been visited by the moving reservoir during the

season of autarcesis (winter and spring) a wave of immunization would result which would render that community relatively free of the disease for a time. Of course many communities may pass through

FIGURE I—This represents a hypothetical community of 100,000, in which initial infestations with the virus of poliomyelitis take place with an even frequency throughout the year, and in sufficient numbers to "saturate" the population in the course of an average lifetime of 50 years. ($1/50 \times 100,000 \times 1/12 = 167$ infestations per month.) This implied rate of dissemination is sufficiently rapid to bring about a practically universal immunization.

The solid area on the chart shows the occurrence of a severe epidemic (2 cases per 1,000 population) of recognizable cases which could occur without any increase in the rate of dissemination of the virus. The remainder of the supposedly uniform number of infestations represents, in unknown proportions, subclinical immunizations or abortive attacks.

the summer season when the virus reservoir happens not to be present and remain free of an outbreak, but at the same time there would be an accumulation in the number of non-immunes.

I wish it understood that the conception of the virus reservoir of poliomyelitis which has been outlined is only a probability, but a probability which is in accord with numerous observations at the bedside, on the statistical chart, and in the experimental laboratory, none of which alone would be conclusive, but all together begin to take on a real significance.

This conception of the epidemiology of the disease is presented with the idea that if its validity be supported by further observations, future studies looking to its control could proceed along more clear-cut avenues of approach rather than by chance and laborious exploration of innumerable possibilities. Thus, if this idea of the virus reservoir is correct, there does not appear to be any great promise in attempts to curtail the spread of the virus. From the experimental point of view our present knowledge indicates that artificial immunization, if accomplished, is likely to be by methods too tedious and uncertain for practical application. These studies, therefore, suggest that we should turn from the pursuit of the bacteriology (if this term may be applied to a virus disease) and immunology of the disease to an exploration of its autarcesiology in our search for means of prevention.

Periodic Medical Examination for Bus Drivers

THE sudden illness of a motor omnibus driver led to an accident which only fortunate chance prevented from having fatal results. The possible consequences of such accidents are so serious that the London *Daily Mail* advocates precautions against them. The example of the railways, where drivers are subjected to a searching medical test on appointment, and annually thereafter, is an admirable one. Something of the kind is already done by the London General Omnibus Company, which at least examines its new drivers and insists on a fresh test before a man who has been seriously ill returns to work. But not all the smaller proprietors are quite so careful. The *Daily Mail* advocates a systematic medical test, repeated at regular intervals, for every driver of a public conveyance. Our contemporary might have gone further and advocated the regular medical examination of all drivers of automobiles, public or private.—*Diplomate*, Sept., 1929.

Standardization of the Wassermann Test*

IN 1928, an investigation of some of the more widely used precipitation or flocculation tests was undertaken, since a study of the complement-fixation test did not seem complete without a determination of the comparative value of these fundamentally similar reactions which are being more and more employed as an aid in the diagnosis of syphilis. During 1929, it has been possible to make a more comprehensive comparison of certain of these tests, namely, the Kahn—both the routine and presumptive procedures—the Kline slide test, the Sachs-Georgi reaction, Müller's Ballungsreaktion, Meinicke's Trübungsreaktion, and to a slight extent his Klärungsreaktion.

The routine Kahn precipitation test was studied the most extensively, having been compared with complement-fixation in the examination of 10,455 specimens. The results obtained agreed approximately with those of the test with the cholesterolized antigen in 9,088 instances, or 86.9 per cent. Of the specimens which gave disagreeing results, nearly fifteen times as many reacted more definitely in the test with the cholesterolized antigen than in the Kahn, a large proportion not reacting at all in the latter. The majority of these specimens were from treated cases of syphilis.

Our observation on the relative value of these two tests is in accord with the results obtained in 1926 when Kahn, in coöperation with seven other serologists, tested a series of 252 specimens from persons who had been given careful clinical observation.

The routine Kahn proved slightly more sensitive than the complement-fixation test with the acetone-insoluble antigen in the examination of the series of 10,455 specimens. The majority of the disagreeing reactions, as with the cholesterolized antigen, occurred with serums from treated cases of syphilis.

As the routine Kahn test is slightly more sensitive than that with the noncholesterolized antigen, and entirely different reagents and apparatus are used in it, this precipitation test, or another of corresponding value, might furnish a more satisfactory control for the complement-fixation test with the cholesterolized antigen than does the one with the non-cholesterolized antigen.

* Abstract of Progress Report, presented to the Laboratory Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

Kahn's presumptive precipitation procedure was compared with the routine Kahn procedure and with the complement-fixation test with the cholesterolized antigen in examining 1,668 specimens. The results indicate that the presumptive test, although more sensitive than the routine Kahn, is, nevertheless, not so sensitive as the complement-fixation test with which it was compared.

The results with the Kline slide test, Müller's Ballungsreaktion, and the Meinicke Klärungsreaktion were closely in accord with those obtained with the routine Kahn. Results with the Sachs-Georgi test indicated the procedure to be less sensitive than the others studied. The Meinicke Trübungsreaktion did not give satisfactory results in our hands. This may have been due to the use of inactive rather than active serums.

While the investigation made for the Committee on Standard Methods has demonstrated the superiority of the complement-fixation test over the precipitation tests studied, the results obtained with complement-fixation made during the League of Nations Conference in 1928 were, on the whole, much less satisfactory than those reported with the flocculation tests. The methods represented at the Conference, however, failed to incorporate certain procedures that have been found to insure accuracy of results. It may be judged, therefore, that less attention has been given during recent years to the development of the sensitivity of the complement-fixation test abroad than in this country. Not only was there failure to secure reactions with many specimens from cases of syphilis, but, with the exception of two procedures, definite reactions were obtained with specimens from persons without history or symptoms of syphilis. The results with the two methods of complement fixation which gave the most satisfactory reactions were comparable to those secured at the Conference with the Sachs-Georgi test, and were much less accurate than those obtained there with the Müller and Kahn precipitation tests. As the latter has been shown repeatedly to give fewer reactions with specimens from cases of syphilis than a sensitive complement-fixation test, one is forcibly impressed with the need for its standardization, with the incorporation of the procedures found to give the most satisfactory results. If it does not seem feasible at present to recommend for adoption any one method *in toto*, agreement on essentials might be secured.

VENTILATION AND COMFORT

WITH the discovery of more fundamental facts—through the substitution of research investigation for opinion—and a study of the essential factors concerned in the problem of ventilation, progress in air conditioning and air distribution has been phenomenal. A logical standard of ventilation can be determined only by accurate measurements of human comfort and efficiency.

The belief advanced some sixty years ago that the object of ventilation was the removal by dilution with fresh air of organic poisons excreted into the atmosphere from human bodies, is of interest today only because this idea still exists in the minds of some of the laity. The investigations at Breslau, by Flügge and his associates, later confirmed by Hill and Haldane in England, and by Benedict and the New York State Commission on Ventilation in the United States, have shown that human occupancy is insufficient noticeably to change the chemical proportions of the constituents of air.

It is recognized that the most important factor in determining the fitness of air, in the absence of some contaminating source carrying harmful dusts, gases and disease producing organisms, is the maintenance of the physical conditions of the air which favor the normal loss of body heat. By the physical conditions of the air is meant its temperature, moisture content and rate of movement. This conception in its early stages led to overemphasis of one or another of these three physical factors as the most accurate index of comfort. The dry bulb temperature of the air, that is, the temperature indicated by an ordinary thermometer which measures the average effect or intensity of the heat, was assumed at first to be the all important

factor in determining one's feeling of comfort. A dry bulb temperature of 70° was offered as a standard. Later, the reverse was true, and a wet bulb temperature of 56° without reference to the other factors was favored as a more correct index. The wet bulb temperature can be determined from the ordinary thermometer by covering the bulb with a moistened wick, and passing air rapidly over it either by whirling or by means of a small fan. The reading of the thermometer indicates the degree of moistness of the air. Then followed the view that the dew point, or the temperature of the atmosphere at which the moisture begins to be deposited as dew, rather than the wet bulb, was more accurate.

The results of further investigations, principally those conducted jointly by the U. S. Bureau of Mines, the U. S. Public Health Service, and the Research Laboratory of the American Society of Heating and Ventilating Engineers, present evidence establishing the influence on human comfort of all three factors—dry bulb temperature, wet bulb temperature and air movement. This later study has demonstrated the physiological changes which take place in the body, and indicated the length of time human beings can tolerate the various combinations of these physical qualities of the air. Temperature conditions at which fans are desirable are indicated; also when fans will no longer mitigate the heat, and finally when an increase in air currents may even exaggerate the discomfort.

While no single instrument has yet been devised to indicate the comfort of a given atmospheric condition, the above study has developed a single index of expression, by means of what has been called the "effective temperature scale," for the degree of warmth experienced by individuals for equivalent atmospheric conditions. The effective temperature scale was established by experiments with human subjects, and measures the resultant effects of the dry bulb temperature, the wet bulb temperature and the velocity of air on the human senses. Within this scale a zone of comfort has been determined, thus indicating various combinations of the physical factors of air giving uniform feelings of comfort.

Our present knowledge of the problems of ventilation therefore seems to justify the acceptance, as a standard, of the following requirements: The attainment and maintenance of an atmospheric condition in every part of a room occupied by human beings that is free from an excess of dust, disease producing organisms, unpleasant odors and poisons, with suitable air movement, and at a temperature and humidity shown within the comfort zone between 63° and 71° F. effective temperature.

A NEW USE FOR THE MALARIAL PARASITE

THE antagonisms which exist between certain diseases have been observed over a long period of time. We believe that the artificial inoculation with the malarial parasite in the treatment of late syphilis by Wagner-Jauregg was the first instance in which infection with one disease was used to cure another, though the attempted cure of certain tumors by inoculation with the streptococcus or its products is a matter of record.

The most recent development is the use of artificial infection with the malarial organism for the cure of gonorrhea. An observation made in Acre¹ tends to show that in Palestine cases of gonorrhea following a previous infection with malaria cleared up more quickly than usual. The high temperature in malarial attacks is credited with having a beneficial effect, and other similar instances have been recorded.

*The Lancet*² calls our attention to the fact that John Hunter a century ago observed "the suspension or cure of a gonorrhea by fevers." It is also stated that during the past five years several German practitioners have used malarial inoculation with success in the treatment of gonorrhea in adult females.

The average number of days in the hospital in cases of military gonorrhea is said to be 55.7 in England, 51.33 in India, and 46.7 in West Africa where the incidence of malaria is high. It is further stated in the report referred to that neurosyphilis is much more prevalent in tropical towns than in the villages of the same country, probably on account of the greater prevalence of malaria in the villages, approximately 70 per cent of the inhabitants being infected; whereas in the towns, preventive measures and drainage have cut down the incidence of the disease.

These reports are exceedingly interesting in themselves, but have an important bearing on the future health of tropical countries, since there seems to be there, as elsewhere, a drift of the inhabitants from the country to the cities.

THE DOCTOR'S INCOME AND PREVENTIVE MEDICINE

FROM time to time the question is raised as to what effect the extensive program of preventive medicine that is developing in many parts of the country will have on the income of the practicing physicians.

The falling death and morbidity rates in all parts of the country compel recognition of the fact that this question has other than academic significance. Thinking persons realize that the practice of medicine is no more a static condition than any other human relationship. In the evolution of social adjustments, the means and mechanism of furnishing necessary human service must be modified to meet changing conditions.

The shrewd horse trader long ago sold his livery stable and bought a garage. The physician of the kerosene era obtained a large part of his income from the treatment of diphtheria and infantile diarrhea. While preventive medicine has reduced the physician's income from both these sources almost to the vanishing point, the physician of the gasoline age has more practice of a far better kind.

The mathematical demonstration of this statement may be presented with available figures. The last year for which figures on diphtheria rates of the various states of this country are obtainable is 1927. In that year there were 82 cases of diphtheria reported in the State of Michigan for each 100,000 population. A comparison of incomes to the physicians between fees received for the treatment of cases and those paid for the immunization of babies reveals that even where the disease has the above unusual prevalence, preventive medicine is as productive financially as curative medicine. The income from treating 82 cases at \$50 each would be \$4,100. Among each 100,000 population in the State of Michigan in 1927, there were 2,200 babies born. If each of these babies had been immunized at only \$3 each, the income from this practice in 100,000 population would have been \$6,600.

It is also to be noted that these data predicate only the immunization of the new-born, or an equivalent number of persons in the community. There are of course four times as many preschool children as babies, and ten times as many school children. The opportunity for increasing practice by carrying on immunization among the preschool and school populations in the physician's clientele offers an almost unlimited field.

VICTOR CLARENCE VAUGHAN

October 27, 1851 — November 21, 1929

THE death, on November 21, 1929, of Victor Clarence Vaughan, M.D., has deprived American medicine and public health of its foremost leader. He was born on October 27, 1851, at Mount Airy, Mo. From 1874 until his retirement in 1921 he was connected with the University of Michigan, first as student, then as teacher and dean, during which long period he achieved for himself a world-wide reputation as a teacher, scientist and epidemiologist.

Retirement from the University did not close his activities. For several years, as Chairman of the Medical Division of the National Research Council, he resided in Washington. It was there he wrote the two volumes of his splendid work, *Epidemiology and Public Health*. In 1926 he produced his autobiography, *A Doctor's Memories*. In the fall of that year, with Mrs. Vaughan, he went as delegate to the Medical Congress in the Orient, visiting China, Japan and

the Philippines. In the spring of 1927 he suffered an attack from which he never fully recovered.

For twenty years following his graduation Dr. Vaughan was engaged in active medical practice. Nevertheless, his interest always centered in laboratory work. From the beginning he was attracted to chemistry and the chemical viewpoint appeared prominently throughout his subsequent work. His first contribution on the separation of arsenic from other metals appeared in 1875. The action of poisons and their detection fascinated him to such an extent that before long his services were in demand as a medical expert and he became a recognized authority in toxicology.

It was but a step to become interested in sanitary matters. The question of the pollution of wells and water supplies arose, and a chemical examination at that early period was the only means of arriving at a decision. At this time Dr. Vaughan was called upon to investigate the not infrequent poisonings from cheese and other milk products. Though bacteriology was then in its infancy he soon realized that the poisonous products were in some way the result of bacterial action. He was among the first to teach that similar products could be the cause of cholera infantum, and that this disease was therefore due to the contamination of milk. Without fully realizing it, the sanitary chemical work was leading him into the new and broader field of modern bacteriology.

It was soon apparent that the old chemical laboratory was inadequate for pursuing problems pertaining to health and disease. His broad vision indicated the need of a separate institution. Accordingly he appeared before the Michigan Legislature of 1887 and secured an appropriation establishing the Hygienic Laboratory at the University. Some attempts were made in the old laboratory to apply the new science of bacteriology

to the solution of problems arising in the examination of waters, but it was seen that a thorough training in the new discipline was necessary. At that early period this could only be obtained in Germany. Accordingly, Dr. Vaughan spent the summer of 1888 in Koch's laboratory in Berlin, where, under the direction of Carl Fraenkel, knowledge of the new methods was acquired.

The laboratory building was completed in the fall of that year and opened in January, 1889. It was the first in this country which offered systematic teaching of bacteriology to physicians and students. For twenty years Dr. Vaughan was active as its Director. In 1903, he established there a Pasteur Institute. At that time the antirabic treatment could be obtained in but two or three places in the country.

Dr. Vaughan's investigations in the new laboratory covered many fields. At first, the examination of water supplies claimed much attention and he devised what he termed "the Michigan method" of analysis, which made use of the experimental animal as a means of detecting harmful bacteria. His studies on food poisonings were likewise extensive and thorough. He sought the explanation of the germicidal action of normal serum and found it in the complex chemical constituent nuclein. Even more important were his studies upon the nature of the bacterial poisons or toxins. He devised an ingenious "tank" method for growing pathogenic organisms in quantities in order to obtain a sufficient amount of the cells for the study of the bacterial proteins. By this means he was able to break up the proteins into two portions, one toxic and the other non-toxic. He utilized these results in formulating a valuable theory bearing upon the nature of hypersensitiveness and of fevers.

As an earnest and enthusiastic investigator Dr. Vaughan had few equals. His extraordinary capacity for writing found

expression in more than 200 publications, not including his more pretentious works, on Physiological Chemistry, Pto-maines and Leucomaines, Cellular Toxins, Protein Split Products, Infection and Immunity, and Epidemiology. As an editor he founded the *Physician and Surgeon*, the *Journal of Laboratory and Clinical Medicine*, and served as the first editor of *Hygeia*. During his 30 years of service on the Michigan State Board of Health he did much to spread the growing knowledge of sanitation and public health.

During the Spanish War, he saw active service at Santiago where he contracted yellow fever. Shortly after his recovery he was detailed, with Majors Walter Reed and E. O. Shakespeare, to investigate the disease which prevailed in the American camps. The classical report of the Typhoid Fever Commission was largely prepared by him as the sole surviving member. In the World War he again saw service, this time as a member of the Board in Charge of the Communicable Diseases.

Dr. Vaughan's valuable services brought him such well deserved recogni-

tion as the presidency of the American Medical Association, of the Association of American Physicians and of other societies. He was awarded the Distinguished Service Medal, Cross of the French Legion of Honor, and the Kober medal, besides various honorary degrees and memberships in learned societies.

It is as an instructive and inspiring teacher that Dr. Vaughan will be remembered by the thousands of students who had the opportunity and privilege of listening to him. He freely drew upon his experiences in life and made the lectures interesting and forcible by his masterly presentation.

Until his last illness Dr. Vaughan maintained a lively interest in the progress of science and of public health. While he was modest as to his own work he freely recognized merit in others. Personally he was a most lovable man, and his home overflowed with true southern hospitality. He loved his fellow men and gave freely of his time and energy. As a scientist and educator he was among the first. He left an enduring impress in both fields. A great leader, a constructive thinker and a broad idealist is gone.

LETTERS TO THE EDITOR

TO THE EDITOR:

The presidential address of Dr. Nicoll, delivered before the State and Provincial Health Authorities of North America, recently published in your valuable journal, attributes a statement to me to which I desire to take exception.

In his excellent discussion on maternity as a public health problem I am quoted as stating that prenatal care and instruction is an "unessential problem" in the general scheme of securing better maternity care. Probably my personal views on this matter are of little interest to your readers, but I feel that in justice to the subject itself I must contradict the false impression which might be conveyed by Dr. Nicoll's remarks. The incident to which he refers occurred at a hearing on the proposed Newton Bill before a Congressional committee at which I appeared in opposition to this measure. In my argument I stated that prenatal care alone would not solve the problem of the comparatively high morbidity and mortality rates which attend childbirth in this country, but rather that the leading factor in their production was inadequate or poor care in delivery. I also stressed the fact that the Sheppard-Towner activities were centered largely in a multitude of prenatal observations, especially by visiting nurses, without sufficient weight being given to the need for proper attention during labor. Unfortunately the provisions of the Sheppard-Towner Act contribute to this situation.

Adequate prenatal care is not sufficient to improve the mortality from childbearing. A certain number of complications may thus be prevented, but sepsis, for example, which is one of the largest single factors in puerperal mortality, can be but little influenced

by prenatal care. Unfortunately a false sense of security has been developed in the minds of patients and others by the notion that prenatal care is all that is necessary, and provisions for safe delivery are in this way apt to be neglected; but this does not imply that prenatal care is a "non-essential problem," and such a point of view is entirely foreign to my opinion.

The so-called problem of better maternity care is not an easy one to solve and will require the combined thought and effort of the community, the medical and nursing professions, and the individual for its effective handling. Stress must not be laid too strongly on any one phase of the work, for thus a lack of balance and proportion results which is detrimental to any advance in this important field of medicine.

Aside from this misinterpretation of my testimony at the hearing on the Newton Bill, I want to commend the timely and valuable address of Dr. Nicoll, which constitutes another evidence of his deep interest in the problem of bettering the puerperal mortality figures of New York State.

GEORGE W. KOSMAK, M.D.,
Editor, *American Journal of Obstetrics and Gynecology*

TO THE EDITOR:

On page 740 of the July issue of the JOURNAL there appeared an article entitled "Rating Your Milk Supply," by Leonard V. Phelps, in which the author (1) briefly outlined the system in use by the U. S. Public Health Service for computing the milk sanitation ratings of municipalities; (2) pointed out features of the formula for determining the General Municipal Milk Sanitation Ratings which in his opinion make it valueless and the results misleading; (3) sug-

gested a substitute formula for the calculation of the General Municipal Milk Sanitation Rating; and (4) presented a "graphical chart" based on his formula, by means of which General Municipal Milk Sanitation Ratings may easily and quickly be determined.

It has been the practice of the Office of Milk Investigations of the U. S. Public Health Service, in reporting survey results, to give the Retail Raw Milk, the Raw-to-Plant Milk, and the Pasteurization Process Ratings, as well as a General Municipal Milk Sanitation Rating, based upon the three afore-mentioned ratings and the percentage of the total milk supply which was pasteurized. It is the formula developed for the determination of this General Rating which Mr. Phelps criticised.

In deriving its formula for the General Municipal Milk Sanitation Rating I am advised by Mr. Frank that the U. S. Public Health Service proceeded on the assumption that the ideally safe milk supply is one to every quart of which every practicable precaution known to preventive medicine has been applied; that is, a supply every quart of which has been both properly produced and properly pasteurized.

Furthermore, the Service formula assumes that the pasteurization precautions are as important as the production precautions.

A rigid application of mathematics upon the basis of the above assumptions will yield the following formula, which is the U. S. Public Health Service formula criticised by Mr. Phelps:

$$\text{General Rating} = \frac{C \times A\% + D \times B\% + E \times B\%}{2}$$

Where: A = Gallons retail raw milk sold per day
B = Gallons pasteurized milk sold per day
C = Retail raw milk rating
D = Raw milk to plant rating
E = Pasteurization process rating
G. R. = General rating

Mr. Phelps charges that the foregoing formula yields misleading results, because variations in B, or the per cent of

milk pasteurized, vary the General Rating even though the *excellence* of production and pasteurization remains unchanged.

These variations in General Rating occasioned by variations in B per cent are all justified, in the light of the reasoning that a municipal milk supply approaches the ideal in safety in direct proportion to the percentage of it which is both ideally produced and properly pasteurized. In Mr. Phelps's examples in Table II the pasteurization process ratings are constant (80). It seems to the writer to be quite clear that either of the two supplies of which 80 per cent is pasteurized is safer, and quite logical that it should be rated higher than the supply with which it is compared.

In the third portion of his paper, Mr. Phelps presents his version of a formula for determining General Municipal Milk Sanitation Ratings. This is:

$$\text{G. R.} = \frac{A + \frac{B + C}{2}}{2}$$

Where: A = Raw-to-retail rating
B = Raw-to-plant rating
C = Plant process rating
 $\frac{B + C}{2}$ = Combined rating
G. R. = General rating

Nowhere in his paper does Mr. Phelps state that his formula is designed to be used only for determining the ratings in communities in which some portion of the milk is pasteurized. It is logical to assume, therefore, that it can be used to determine general ratings in communities having only retail raw milk supplies, as is frequently the case in small communities.

Suppose, then, the Retail Raw Milk Rating of such a community's supply be 90. The General Rating, according to the Phelps formula, is:

$$\frac{90 + \frac{0 + 0}{2}}{2} = 45$$

This is identical with the result obtained by the use of the U. S. Pub-

lic Health Service formula. It seems, then, that Mr. Phelps has added nothing of value to our machinery for obtaining the G. R. in communities entirely dependent upon raw milk supplies.

Suppose, however, that 5 per cent of the supply (20 gallons of a total supply of 400 gallons—an actual case in an Alabama community) were pasteurized, and that the Raw-to-Plant and Plant Process ratings were those given in Mr. Phelps's examples—80 and 80 respectively. The General Rating of this community supply would then be:

$$\frac{90 + \frac{80 + 80}{2}}{2} = 85$$

According to Mr. Phelps's conception the whole community milk supply is nearly twice as safe because 5 per cent of it is pasteurized! This does not seem logical.

According to the U. S. Public Health Service formula, the General Rating of this community supply would be:

$$\frac{90 \times .95 + 60 \times .05 + 80 \times .05}{2} = 46.75$$

This slight increase in General Rating appears to be a far more logical result of the pasteurization (somewhat imperfectly) of only 5 per cent of the total municipal milk supply.

Assuming, however, that Mr. Phelps intended his general formula to apply only to cities in which at least some pasteurized milk is sold, it is nevertheless mathematically faulty, as is shown by the following examples, in which the volume of milk and the A-B-C ratings are constant, but the percentages of milk sold raw and pasteurized are reversed.

City A consumes 10,000 gallons of milk per day, of which 9,900 gallons is pasteurized, with B and C ratings of 80 each. The other 100 gallons are raw milk of low quality and high bacterial count, with an A rating of 50, a situation frequently found where pasteurization is not compulsory.

City B consumes 10,000 gallons of milk per day, of which only 100 gallons are pasteurized, with B and C ratings of 80 each. The other 9,900 gallons are raw milk of low quality and high bacterial count, with an A rating of 50, a situation not infrequently found, wherein one small plant is trying to introduce pasteurized milk.

Obviously in City A 99 per cent of the milk is moderately safe, whereas in City B 99 per cent of the milk supply is 50 per cent unsatisfactory. Yet the Phelps formula would give both cities the same General Rating, namely, 65.

The U. S. Public Health Service formula, however, would give City A a General Rating of 79.45, and City B a General Rating of only 25.55. These are obviously reasonable ratings in view of the contrasting circumstances, and illustrate the utter necessity of including the percentage of milk pasteurized in the formula.

If the foregoing reasoning is correct, the conclusions of Mr. Phelps are unfounded, and his objections and proposed substitute are unsound.

C. A. ABELE,
Director of Inspection
State Board of Health
Montgomery, Ala.

TO THE EDITOR:

The U. S. Public Health Service has issued a statement concerning the General Rating, which is derived from the use of their formula, "that a 100 per cent General Rating means that all of the community's milk supply has been both properly produced and properly pasteurized." It would seem logical then to assume that a milk supply having a G. R. higher than another would be one that was better produced and better pasteurized. But this is not the case. Table II, page 743 of the July issue of the JOURNAL, shows an example in which a milk supply may either be produced or pasteurized one-half as well

as another and still receive a higher G. R., simply by increasing the percentage of the total milk supply pasteurized. My critic attempts to justify this by stating that a milk supply approaches the ideal in safety in direct proportion to the percentage of it which is both ideally produced and properly pasteurized, and that a higher rating should be given that having the larger percentage pasteurized. However, this statement does not deny the fact that the G. R. does not show the excellence of production or pasteurization.

I did not undertake to discuss in my article what constitutes the ideal milk supply, but merely what I considered defective in the U. S. Public Health Service formula.

My critic's statements would lead one to believe that it was not intended that the federal G. R. should show how properly the milk had been produced or pasteurized, but rather the "safety" of the supply, the safety being dependent upon the degree of excellence with which the milk had been both produced and pasteurized, and what percentage of the supply had been pasteurized.

When a rating stresses a particular subject, it is no longer a general rating. I did not state that a special rating, in which pasteurization was stressed, should not give added credit for increases in the percentage of the supply pasteurized. My contention was that pasteurization should not be stressed in a general rating formula, and especially when the stressing of it makes it impossible to determine from the G. R. the excellence of production and pasteurization, and the manner in which a community has complied with the dairy regulations as given in the Standard Milk Ordinance.

Assuming that the federal G. R., as my critic has implied, was intended to show the safety of a community's milk supply, and not how properly it had been produced or pasteurized, it can

easily be shown that in many instances it does not show safety. One G. R. higher than another does not necessarily indicate a safer supply.

For example, in Table II, an A-B-C score of 80-60-80 where 20 per cent of the supply was pasteurized gave a G. R. of 46.0, while another 40-30-80 when 80 per cent of the supply was pasteurized gave a G. R. of 48.0. While the latter supply had a higher G. R. than the former, because of the higher percentage of milk pasteurized, the raw milk going to the plant was of such a poor quality that pasteurizing would not change it into a good milk, nor would it compensate for its improper production.

To pasteurize a poorly produced milk will not make it safe, and to pasteurize improperly a properly produced milk is much worse than not pasteurizing it at all.

Since, in the federal formula, production of milk going to the plant and pasteurization are given equal weight, it would seem that the same G. R. would have resulted had the production to plant score been constant at 80 in both cases, and the pasteurization process been rated 60 and 30 respectively. A raw milk properly produced is safer than one improperly pasteurized.

Just what score would indicate improper production or improper pasteurization, may be a matter of opinion, but certainly no one will deny that a score of 30 or less would do so.

It might be logically assumed, providing my critic's implied interpretation of the intended meaning of the federal G. R. is correct, that two milk supplies having equal general ratings were equally safe. Such is not the case.

TABLE A

Milk Supply	A-B-C Score	Per cent		General Rating
		Milk Pasteurized	Milk Raw	
I	80-75-30	90	10	51.25
II	80-75-80	30	70	51.25
III	80-70-20	90	10	44.5
IV	80-70-80	14	86	44.9

A supply with an A-B-C score of

80-75-30 would give a G. R. of 51.25 when 90 per cent of the milk was pasteurized, while another having a corresponding score of 80-75-80 and 30 per cent pasteurized would also have a G. R. of 51.25. Both supplies are produced equally well, but the first is improperly pasteurized, yet it is accorded a G. R. equal to that of the second simply because 60 per cent more of the supply is pasteurized.

It cannot be reasoned that the two supplies are equally safe, yet the federal formula gives them equal ratings, indicating that they are equally safe. A second example of this type may be seen in Table A under supplies III and IV, in which the general ratings are almost equal. Since values for B and C in the A-B-C score may be interchanged without affecting the G. R., it can be seen that both of these examples might have had improperly produced supplies instead of ones that were improperly pasteurized.

I suggested in my article the following formula which would show how well a community was complying with the regulations of the ordinance:

$$\text{G. R.} = \frac{A + \frac{B + C}{2}}{2}$$

Where: A = Retail raw rating
 B = Raw-to-plant rating
 C = Pasteurization process rating
 G. R. = General rating

While it is true that I did not state that the suggested formula was designed to be used only in communities in which some portion of the milk was pasteurized, the context of my article made it

the only logical conclusion. Twice on page 746, and at least once on page 743, of the July issue of the JOURNAL, it was plainly stated that it was my opinion that the G. R. should show compliance with dairy regulations, and only that. Obviously a supply in which none of the milk was pasteurized would have a G. R. identically the same as the retail raw score.

Nowhere did I state that my formula would give a G. R. showing "safety" of the milk supply. My critic's assumptions and examples are therefore irrelevant and will not be discussed.

I suggested a formula which would show in the G. R. compliance with regulations as given in the Standard Milk Ordinance, and that only, not because a formula capable of producing a special rating showing the safety of the milk supply would not be desirable. I did not intend to imply that a formula designed to show safety of the supply should not give added scoring to supplies showing a larger percentage of milk pasteurized than another, providing that the supplies had both been properly produced and properly pasteurized.

I have shown that the federal formula does not give a G. R. which shows how properly a milk supply has been both produced and pasteurized, neither does it show "safety" of the milk supply, nor to what degree a community is complying with the regulations of the Standard Milk Ordinance.

LEONARD V. PHELPS,
 City Bacteriologist and Chemist,
 Bluefield, W. Va.

ASSOCIATION NEWS

1929 ANNUAL MEETING PROCEEDINGS

THE 58th Annual Meeting of the American Public Health Association is a milestone in the progress of this organization. Several important changes in the Constitution and By-laws were adopted in accordance with recommendations of the Committee on Revision of the Constitution and By-laws and the Committee on Coöperation, Development and Finance, after an exhaustive study of the activities, policies, and future opportunities of the Association. The reports of officers and committees were constructive and indicative of progress.

The program arranged by the Central Program Committee included 47 sessions and 180 papers, exclusive of the programs of twelve related organizations which also met in Minneapolis at the same time. The annual meeting registration numbered 795 members and 569 guests. Special representatives were present from China, Hawaii, and the Philippine Islands. An unusually full program of general and section meetings attracted large audiences. The educational exhibits and demonstrations were in general considered to be above the average.

EXECUTIVE BOARD

The Executive Board consisting of 10 members held a busy session when reports were received from the officers and 9 major committees.

The Committee on Exhibits reported an income of \$16,000 from Annual Meeting exhibits. Seven commercial exhibits were not accepted.

Requirements for affiliated societies were discussed by the Executive Board, but were referred to the incoming board for further consideration.

The Treasurer's report showed a more healthy financial status than in several previous years. According to the auditor's statement as of August 31, 1929, the net worth of surplus of the American Public Health Association was \$26,747.85, with total assets of \$58,127.92 and total liabilities of \$31,380.07. The Executive Secretary's report will be reviewed in subsequent paragraphs.

GOVERNING COUNCIL

The Governing Council held four meetings, in addition to a brief meeting of the incoming council, with gratifying attendance at each meeting of from 38 to 50, including section officers and representatives of affiliated societies averaging 43 Fellows.

The business of outstanding importance related to amendments to the Constitution and By-laws. These amendments will soon be published in detail in the JOURNAL. One of the principal changes in the Constitution provides that the officers of the Association shall be a President, a President-elect, three Vice-Presidents, an Executive Secretary, a Treasurer, and the Chairman of the Executive Board. The addition of the offices of President-elect and Chairman of the Executive Board should aid in long term planning and strengthen the administration of Association affairs. The officers, with the exception of the Chairman of the Executive Board and the Executive Secretary, are elected by written ballot of the Governing Council, while the Chairman of the Executive Board and the Executive Secretary are elected by the Executive Board, which board defines the duties and authority of these respective offices. The amendments also provide that at

the annual meeting the Governing Council shall determine in general outline the allocation of association moneys in the budget, and shall receive from the Executive Board a definitely formulated statement of a program of the major activities proposed for the ensuing year.

One of the important amendments to the By-laws provides for four standing committees of the Association in place of a large and indefinite number as previously. These committees are as follows:

- Committee on Fellowship and Membership
- Committee on Meetings and Publications
- Committee on Administrative Practice
- Committee on Research and Standards

Certain problems of the Association may be handled through sub-committees or section committees. Section Councils and officers remain essentially as before, but it is provided that sections submit annually to the Governing Council through the Executive Board a report of the transactions of the section during the past year, and of the plans, scope and policy for the succeeding year—as well as advise with respect to the appointment of technical committees, sub-committees or section representatives on committees of the Association.

During the meetings of the council, 57 applications for Fellowship and 30 applications for Life Membership were approved. The report of the Committee on Resolutions has already been published in the JOURNAL.

ASSOCIATION COMMITTEE REPORTS

ADMINISTRATIVE PRACTICE

The past year has been one of great activity for the Committee on Administrative Practice, continuing its work of collecting and analyzing material relating to the administration of public health work. Its sub-committees have issued progress and final reports which have been received with keen interest.

The Sub-Committee on Record Forms has issued for experimental use, in line

with its adopted policy, a complete set of tuberculosis clinic records. The publication of these was made possible through coöperation and financing in part by the National Tuberculosis Association.

A second school health examination form, to be used in those communities providing for medical examinations, has been prepared by the committee and presented to the public by publication in the *American Journal of Public Health*.

The Sub-Committee on Model Health Ordinances has presented its first progress report, which lists the minimum requirements for local health laws and will serve as a guide to the formulation of the basic laws applicable to county, district and municipal health organization and practice.

The Sub-Committee on Organized Care of the Sick, which it will be remembered has representatives from both the public health group and the hospital group, has continued its consideration of this important question, and has published in the JOURNAL,* a thought-provoking list of questions covering "What Public Health People Should Know about Hospitals and Clinics in Their Community." The committee is at present engaged in a detailed study of the Care of Communicable Diseases in General Hospitals. A preliminary report of this study was made two years ago, which developed considerable interest both in the public health and the hospital fields. The present study is to show in some detail the advantages and difficulties of caring for communicable diseases in general hospital plants.

Under the direction of the *Sub-Committee on Appraisal of City Health Work*, the *Appraisal Form for City Health Work*, revised last year, has been distributed and put into actual practice beginning January 1, 1929. Its reception has been even more favorable than previous editions. Local health officers

* Apr., 1929, p. 397.

are expressing their approval of the many improvements made in the objectivity of the subject matter. There are, however, a number of items which are still subject to change.

The American Social Hygiene Association has published with descriptive comments the section of the Form dealing with Venereal Diseases, to stimulate greater interest among constituent members and others interested in the service.

The National Tuberculosis Association recently reprinted those items which deal directly with tuberculosis services and the related activities which frequently form a part of the program of local tuberculosis associations.

The National Committee for Mental Hygiene is distributing for experimental use the section dealing with Mental Hygiene services, prepared at the time of the last revision of the *Appraisal Form*, but not a part of the printed form.

The study of rural health work, undertaken last year on a grant from the Commonwealth Fund, has been continued under the *Sub-Committee on the Appraisal of Rural Health Work*. Up to the end of May, 1929, 15 counties in 9 states had been studied, covering a wide range of organization of state and local services, geography, climate and topography, and population.

As reported a year ago, studies of state health departments were carried on and reports prepared at the request of three state commissioners of health. The studies of last year have been condensed and will be printed by the Publication Division of the Commonwealth Fund, with the permission of the health officers concerned. This publication will be available for state health administrators, students and others interested in public health work.

The *Sub-Committee on Health Department Reports* has continued its activity, working out in tabular form and content the statistical tables recommended for inclusion in annual reports.

The adoption of recommendations* of this committee by health departments throughout the country would insure more satisfactory statistical material than is now available.

Since the last meeting the plan for the Health Conservation Contest, to be conducted under the auspices of the Chamber of Commerce of the United States, has been developed and the contest launched. The details of the plan and the schedule for grading cities entered in the contest have been discussed with three groups of health officer representatives, western, eastern and central divisions. The representatives in each group were selected by the members of the Health Officers Section of the Association.

The *Sub-Committee on Public Health Nursing* is focusing its attention on: (1) the possibility of having some qualitative as well as quantitative measure of nursing service, (2) gathering material relative to the merits or demerits of the various systems of administering school nursing, and (3) material relative to the function and the administration of public health nursing in state departments of health.

The program of *Coöperation with the General Federation of Women's Clubs* carried on for the past three years has received considerable attention during 1929, with profit, we believe, both to the Association and to the Federation.

The Field Director was made a member of the Advisory Board to the Division of Public Health, Child Welfare and Community Service of the Public Welfare Department of the Federation, and has assisted in the planning of a health program covering community studies, health institutes, and general education in the field of maternal hygiene.

The *Field Service* of the Committee on Administrative Practice has been

* See page 34, this issue, for Report.

continued along the lines which have become fairly well crystallized, that is, rendering service to cities or communities approximately at cost. The communities studied so far this year are:

<i>Counties</i>	<i>Cities</i>
Pitt Co., N. C.	Fargo, N. D.
Clarke Co., Ga.	Quincy, Mass.
Rutherford Co., Tenn.	Providence, R. I.
Cattaraugus Co., N. Y.	Honolulu, Hawaii
Marion Co., Ore.	Milton, Mass.
	Nashville, Tenn.

In Providence and Honolulu certain aspects of hospital problems and the care of the sick were included in the study. The cities of the Demonstration Areas have been included at the request of the Commonwealth Fund and the Milbank Memorial Fund, as a part of their service to these communities. Pitt County, which was as already stated studied as a prize award, is the only survey which was not paid for by the community or an interested agency.

CHAUTAUQUA HEALTH PROGRAM

The Chautauqua Health Program Committee reported a very successful season, with many practical results. In 85 towns of 10 states, the health lecture of the Chicago Seven-Day Redpath circuit reached 72,700 people. In addition, 2,150 people were reached in two other communities through two independent Chautauqua programs. The number of addresses, outside of professional engagements, which the lecturer gave before luncheon and civic clubs and church congregations, would increase the number of his hearers several hundred more.

In any consideration of the health program, the children's Chautauqua must not be disregarded. Its program was given on the afternoon following the health lecture and it attracted fully as many people, particularly parents and relatives, as the evening lecture.

A full-time health Chautauqua director visited the capitals of the states on

the circuit, obtained the hearty cooperation of the state health officers and investigated conditions in the Chautauqua towns previous to the lecture. These activities proved most fruitful in providing the lecturer with advance information regarding problems to be stressed or work to be featured. The Tennessee State Health Department sent out a prospectus of the plan and a request for relevant information to health officials and civic minded persons in towns under its jurisdiction. This was a valuable preliminary. It established the status of the program and led to an intelligent understanding of it. The Kentucky Board of Health gave a summary of health conditions in each town and the points to be emphasized. The Indiana State Health Department sent a representative to the towns about two weeks before Chautauqua arrived.

When such solid and practical information concerning the policies of the State Health Department, as well as particular local health problems from the state's viewpoint, had been obtained by the director, a personal visit was made by him to each place where such was advised. In Georgia 5 towns were visited; in South Carolina 8; in North Carolina 7; in Tennessee 12; in Kentucky 14. These calls always resulted in a much better understanding of local health matters than could be gotten in any other way. It is felt that individualizing the lecture to the locality gave it a force and practical interest that added tremendously to its value.

E. L. Bishop, M.D., Commissioner of Health, State of Tennessee, after recounting in detail the stimulating effect on the public health movement in his state directly due to the Chautauqua Health Program, summarized as follows:

In our state the program was largely instrumental in bringing about the establishment immediately of two county health departments, the quite probable establishment of two additional departments and the possible

establishment of still another county health department. Mr. Snyder's visit to Tennessee was one of the most worthwhile educational projects and bore more substantial fruit than any other single project it has been our good fortune to have.

In addition to the above committees, progress reports were made on *Census of Public Health Workers*, *Federal Health Legislation*, and *Dairy Products*. The report of the *Committee on Annual Meetings*, recommending Fort Worth as the next meeting place, received favorable action. Attention was called to the necessity for vigorous section activity in developing a successful annual meeting, and the Executive Board was requested to consider the provision of a moderate budget for each section to aid in the work.

EDITORIAL COMMITTEE

Readers of the JOURNAL may be interested to note the increasing appreciation shown in the magazine by subscribers as well as by members. The average monthly paid circulation of the JOURNAL for the 12 months ending August 31 was 5,624 copies compared with 4,817 copies for the same previous period.

JOURNAL management is to provide each month articles sufficient in number and in length to satisfy all the interests in the Association and still keep within the budget. The only solution to this problem is more short articles.

At the beginning of the year the policy was adopted of promoting the demand for reprints from the JOURNAL, believing that this would give the material wider circulation and increase interest in the JOURNAL. This has resulted in orders for reprints of 60 articles from the January to August, 1929, issues and total sales of 144,275 reprints.

The outstanding need of the JOURNAL is for a larger budget. In spite of the fact that the present arrangement of a part-time editor is working satisfactorily, the importance of the JOURNAL in the Association's affairs merits full-time editorial service. The report of the Managing Editor shows that the JOURNAL is more than paying its way and the Editorial Committee believes that a greater share of the profits should be put into the JOURNAL. There is need not only for more editorial service, but also for a larger JOURNAL. Less than

AVERAGE MONTHLY CIRCULATION (PAID AND FREE)
FOR EACH YEAR ENDING AUGUST 31

	Members	Subscriptions	Free	Total
1924	3,016	787	87	3,890
1925	3,095	842	108	4,045
1926	3,189	947	129	4,265
1927	3,392	1,045	132	4,569
1928	3,562	1,255	166	4,983
1929	3,952	1,672	199	5,823

The income from advertising for the 12 months ending August 31, 1929, was \$25,078.07, compared with \$13,378.04 for the previous year. This increase, accomplished without an increase in advertising rate, is in part due to the taking over of the business of *The Nation's Health*.

One of the most difficult problems of

35 per cent of the 199 papers and reports presented at the Chicago meeting were published. This low figure is due in part to the unusually large program at that meeting, but the figures for 1926 and 1927 were 44 per cent and 42 per cent respectively. Roughly two-thirds of the JOURNAL during the year is given to Annual Meeting papers and Associa-

tion reports. To raise this figure materially would further reduce the space now available for timely contributed articles.

EXECUTIVE SECRETARY'S REPORT

Reference has previously been made to the financial status of the Association as shown in the Treasurer's report. An income for the fiscal year 1929 of \$117,348, an expense of \$104,881, and a net gain of \$12,467, compares with an income of \$31,187, an expense of \$29,566, and a net gain of \$1,621 in 1924.

Proportionally the income from membership dues, sales of publications, advertising and such basic sources is steadily decreasing. Actually the income from these sources in 1928 was three times as great as it was in 1923. Seventy per cent of the Association's total income in 1928 was from these sources as compared with 95 per cent in 1924. The income from grants is as rapidly increasing, representing 5 per cent in 1924 and 30 per cent in 1928. The proportion will be still higher in 1929. This changing basis of income

REGISTRATION OF MEMBERS AND GUESTS

Year	City	Total Registration	Number of Members	Number of Guests	Per Cent Guests	Per Cent of Members of the Association Registered at Meeting
1924	Detroit	894	517	377	43	16
1925	St. Louis	876	528	348	46	16
1926	Buffalo	1474	821	653	45	25
1927	Cincinnati	1158	795	363	31	23
1928	Chicago	2577	1057	1520	59	28
1929	Minneapolis	1364	795	569	42	20

must be recognized in the future planning of the Association.

Membership—On September 1, 1929, there were 3,945 members of all classes in good standing as against 3,735 on September 1, 1928. This represents a gain of 645 new members and a loss of 435, making a net gain of 210 for the previous 12-month period.

Affiliated Societies—There are at present 14 affiliated societies, 3 having been affiliated at the last Annual Meeting. One application (Georgia) is awaiting action at this meeting.

In addition to supplying reprints and copies of its own publications, the Association has continued its *Book Service*, supplying information on public health books to members and facilitating the purchase of health books by the members.

Syndicated Public Health Bulletin—The subscription rates were increased in January approximately 25 per cent, with no loss in subscribers. There has been a very insistent but small demand for this service.

Annual Meeting—It is a common observation that Annual Meetings are growing in size and complexity. The growing complexity is in a large measure due to the increasing number of smaller organizations meeting with us. The financing of meetings is becoming a large problem. A special memorandum on this subject to the Executive Board was considered.

Last year the Executive Board decided to give up the policy of looking to Annual Meeting cities to carry a major portion of the costs of Annual Meetings, and to adopt the policy of financing

INCOME FROM ANNUAL MEETINGS

City	Year	From Exhibits	No. Booths Sold	From Local Committee	Total
Detroit	1924	\$2,964.50	26	\$4,621.38	\$7,585.88
St. Louis	1925	2,319.75	30	6,000.00	8,319.75
Buffalo	1926	4,358.46	33	3,500.00	7,858.46
Cincinnati	1927	7,610.00	33	00.00	7,610.00
Chicago	1928	20,254.85	91	744.24	20,999.09
Minneapolis	1929	14,260.00	65	00.00	14,260.00 (to Aug. 31)

meetings out of the sale of exhibit space and other income. In Chicago considerable progress was made in this direction, and this year the Association will carry its full share of annual meeting expense.

Chautauqua—In addition to its usual administrative duties the Executive Office has administered the Chautauqua program carried on again this year through a grant of \$15,000 from the Milbank Memorial Fund. One field worker has been employed for this service and the report on this project has been presented by the Chautauqua Health Program Committee.

Field and Organization Contacts—A curtailed staff, a decreased budget and administrative problems have limited the field and organization contacts of

the Executive Secretary. He has, however, represented the Association on the Executive Committee of the National Health Council, on the Board of Directors of the Joint Vocational Bureau, at the Conference on Public Health of the American Medical Association, and on the Board of Directors of the American Association for the Advancement of Science.

This report would be incomplete if it did not also record the fact that the Executive Secretary's office has given much assistance during the year to the work of several Association committees, especially the *Committee on Coöperation, Development and Finance*, and if it did not acknowledge particularly with deep appreciation the invaluable assistance of a devoted staff.

NEW MEMBERS

- J. A. Baker, M.D., Middlebourne, W. Va.,
County Health Officer

INTERNATIONAL HYGIENE EXHIBITION

There will be held in the city of Dresden, Germany, from May to October, 1930, an International Hygiene Exhibition, sponsored by the Deutsches Hygiene-Museum. The opening of this exhibition will also mark the dedication of the new building for the Deutsches Hygiene-Museum.

It will be recalled that this is the organization which was responsible for the exceedingly interesting educational hygiene exhibit shown in Dusseldorf and in other European cities in 1926.

Many European countries have al-

ready reserved space in this exhibition, and Dr. Arthur Schlossman of Dusseldorf, a member of the Board of Directors of the Deutsches Hygiene-Museum, has just visited America where he has discussed with a number of national health organizations, official and unofficial, the possibility of an American exhibit in the exhibition.

Further information concerning the proposed exhibition can be secured by addressing the Managing Editor of the *American Journal of Public Health* and *The Nation's Health*.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Full-time Health Protection—
Concrete evidence that fewer mothers and infants die among those reached by full-time modern health service will be found in figures recently compiled for the Child Health Demonstrations of the Commonwealth Fund:

During the 4-year period covered by this special study there were 10,444 births in the four demonstration communities. In 2,518 cases, about one-fourth

month in comparison with 297 in the group not served.

The comparative mortality and still-birth rates are given in Table I.

In these four communities 6,234 infants between 1 month and 1 year of age had either field nursing service or medical supervision in health centers, or both, while 3,425 infants did not have such care. There were 113 deaths in the group served and 163 in the group

TABLE I

	Maternal Deaths per 1,000 Births		Stillbirths per 1,000 Births		Infant Deaths under 1 Month per 1,000 Live Births	
	Under Care	Not under Care	Under Care	Not under Care	Under Care	Not under Care
<i>All Demonstrations</i>	3.2	7.6	25.8	48.4	16.3	39.4
Fargo, N. D.	3.9	5.4	17.0	44.2	9.3	49.4
Marion County, Ore.	0.0	3.8	6.2	37.5	16.7	31.4
<i>Clarke County, Ga. Total</i>	6.5	15.2	30.4	70.1	33.6	46.2
White	4.8	6.3	9.7	44.0	29.3	31.7
Colored	7.9	28.6	47.6	109.6	37.5	69.7
<i>Rutherford County, Tenn. Total</i>	2.5	8.3	43.1	49.3	12.9	39.2
White	1.8	7.3	38.9	46.7	9.2	34.4
Colored	4.0	11.5	52.6	57.4	21.4	54.8

of the total, nurses of the health department gave prenatal instruction and supervision in coöperation with the family physician. In the group under such supervisory care there were only 8 maternal deaths in comparison with 60 in the group not served, 65 stillbirths in comparison with 383 in the group not served, and 40 infant deaths under 1

not served. The comparative mortality rates in this age group (calculated in relation to the number of infants still alive at 1 month of age) were as shown in Table II.

Where care was given the infant mortality rates were especially low for congenital causes, respiratory diseases, diarrhea and enteritis. Among infants

TABLE II

	Under Care	Not under Care
<i>All Demonstrations</i>	18.1	47.6
Fargo, N. D.	16.5	80.7
Marion County, Ore.	4.3	25.9
<i>Clarke County, Ga. Total</i>	19.5	71.8
White	7.6	49.1
Colored	34.4	114.5
<i>Rutherford County, Tenn. Total</i>	31.5	57.8
White	28.9	48.6
Colored	39.4	83.7

under 1 month of age the mortality rate from congenital causes was 11.5 for the group served and 31.0 for the group not served. Among the older infants the rates for the group served were 5.0 for respiratory diseases and 3.8 for diarrhea and enteritis, as compared with 14.3 and 13.4, respectively, for the group not served.

These figures are supporting evidence that a favorable showing can be secured in the form of low mortality rates where preventive maternity and child health services are organized.—*Health Officer's News Letter*, A. P. H. A., Nov. 22, 1929.

Full-time Health Protection in Kansas—In addressing the annual meeting of the County Commissioners in Kansas on November 20, Earle G. Brown, M.D., Secretary of the State Board of Health, cited the value of efficient county health work in the control of communicable diseases. In Jefferson County there was a full-time County Health Department from August 1, 1925, to June 30, 1929. The accompanying table offers a comparison of the number of deaths in this district from certain communicable diseases for the 4-year period immediately preceding the organization of the full-time health organization and for the 4-year period during which the full-time health service was in effect.

The difference in the number of deaths in the two 4-year periods repre-

sents an economic saving of approximately \$125,000 for communicable diseases alone. In addition to this there has been a physical inspection of school children with correction of defects; water, milk and food sanitation; infant and maternal hygiene and other recognized health activities tending toward the promotion of positive health habits.

County-Wide Health Survey—A sanitary and health survey was made during 1927 and 1928 of Darke County, O., 71 individuals participating in the field work. Every house, urban or rural, in the entire county was visited. The 1920 census gave a population of 42,911. There are 42 physicians in the county and 134 schools with a total enrollment for 1928 of 8,668. One small hospital with 20 beds is located in Greenville. The county has no tuberculosis hospital and no isolation hospital.

The full-time staff of the County Health Unit numbers 8: the Health Commissioner, his Deputy, a sanitary inspector, a supervising nurse, 3 field nurses and 1 clerk. There are also 3 part-time assistants. In 1927 the per capita expenditure was 42 cents and this was increased in 1928 to 46 cents.

During the survey 10,782 houses were located. It was found that of 31,791 persons actually dealt with in the survey, 3.3 per cent had had smallpox, 27.1 per cent had been successfully vaccinated and 69.5 per cent were unprotected. Approximately 80 per cent of the school children were unprotected. The county is therefore wide open to smallpox.

It was found that 6.4 per cent had had typhoid fever and 5.4 per cent scarlet fever. Undulant fever is a real danger as indicated by the large percentage of milch cows shown to be infected with *B. abortus*. A definite diagnosis of undulant fever was made in 10 human cases. The county being largely rural, more than 75 per cent of the people are

	1921-1924	1925-1929

served with outdoor closets of the surface or earth vault type. Of school children, 45.6 per cent showed physical defects.—Reference M. E. Barnes, *Pub. Health Rep.*, 44: 2315 (Sept. 27), 1929.

Tuberculosis Program for Children—Since 1924 approximately 100,000 children have been examined by the Massachusetts Department of Public Health. An analysis of the available figures shows that when children begin school life 20 per cent are infected with

tuberculosis, at age 10 there are about 28 per cent infected and at 15 approximately 35 per cent. It has been found that children are infected with the tubercle bacilli to the same degree regardless of nutrition or nationality, if they are exposed to an open case of tuberculosis. When there is definite contact with pulmonary tuberculosis, children are almost always infected.—Henry D. Chadwick, *The Ten Year Program for Children, The Commonwealth*, July-Sept., 1929.

LABORATORY

C. C. YOUNG, D. P. H.

A RAPID METHOD FOR PIPETTING BROTH IN MEASURED AMOUNTS

G. D. CUMMINGS

*Bureau of Laboratories,
Department of Health, Lansing, Mich.*

EVERY media division has had an order at some time for tubes containing measured amounts of broth. When such an order is received it means that the broth must be measured out by burette or by hand. Either method is troublesome and time consuming when the order is large. In this laboratory we employ the set-up illustrated in the accompanying photographs. Figure I shows in detail the parts needed, while Figure II is an assembled picture of the actual operation. Figure I, A, is the set-up ordinarily used for tubing broth in unmeasured amounts so that B is the only new addition.

The operation of the pipette requires two people, one to operate the pipette, the other to hold the tube. With both Mohr pinchcocks closed the funnel is

filled with the broth to be tubed. The pipette is an ordinary 10 c.c. or other volume pipette, with a small orifice blown on the top side of the upper end. The operator opens the top pinchcock to allow the broth to fill up the pipette to the zero mark. The top pinchcock is then closed and the bottom one opened to allow the broth to run off in the required amount. The small orifice at the top of the pipette eliminates the possibility of a vacuum and allows the broth to flow freely.

If the operator holds the pipette so that the broth runs in at an angle (Figure II), there is no danger of loss of material through the orifice. With a small amount of practice the operators can run off tubes with great facility.

Such a set-up may be used with any

FIGURE I

FIGURE II

sized pipette, Mohr or transfer, and with any funnel. We have found by actual timing that we can run off a given batch

of tubes with this arrangement in about one-eighth of the time usually consumed, with equal or greater accuracy.

THE CAUSE OF MUSTINESS IN EGGS

M. P. SPANSWICK, F. A. P. H. A.

Bacteriologist, State University of Iowa, Iowa City, Ia.

WHILE making bacteriological examinations of eggs for a commercial packing concern in Des Moines, Ia., the author isolated an organism which is the causal agent of "must" in eggs. Commercially, musty eggs present a real problem, since one such egg will render all with which it comes in contact unfit for use in the preparation of food products.

The organism is a very small, motile, Gram-negative, aerobic, non-sporulating bacillus, growing profusely on agar in 5

days at room temperature, but not at 37° C. It produces a very characteristic musty odor. It does not liquefy gelatin, reduce nitrates, produce indol, or change litmus milk. Although moderately acidophilic when first isolated, repeated subculturing has gradually increased its alkaline tolerance. It still retains its ability to produce its characteristic odor.

Fresh eggs inoculated with broth cultures developed the typical musty odor in 5 days. No change was noted in the

appearance of the eggs except a slight iridescence in the white in some instances. The organism was recovered in pure culture from all the eggs inoculated.

According to the classification adopted by the Society of American Bacteriologists, the organism is of the *Genus Achromobacter* but differs from the species described. When this work was started

in 1926 no mention had been made in the literature of an organism causing must in eggs. Since then A. W. Turner¹ of Melbourne, Australia, has described apparently the same organism. He proposes to call it *Achromobacter perolens*.

MINUTES OF THE MEETING OF THE COMMITTEE ON STANDARD METHODS OF THE LABORATORY SECTION

A MEETING of the committee was held at the Hotel Curtis, Minneapolis, on October 1 at 6:30 P.M. The following were present: E. O. Jordan, *Chairman*, R. G. Perkins, L. M. Wachter, W. H. Frost, A. Wadsworth, W. H. Park, N. MacL. Harris, and J. F. Norton, *Secretary*. Drs. Gilbert and Reddish were present as referees.

Dr. Ruth Gilbert, the referee on the Standardization of the Wassermann Test, presented a progress report dealing with comparative tests between the complement-fixation and precipitation methods. The report was presented in full at a session of the Laboratory Section. It was voted to recommend that an abstract* of Dr. Gilbert's report be published in the *American Journal of Public Health* and that permission be given her to publish in full, elsewhere.

Dr. Reddish presented a brief report as referee on the Standardization of Methods for testing Disinfectants. He recommended that his modification of Hygienic Laboratory Method be recommended by the Committee to the Association. No action was taken on the recommendation.

The report of C. T. Butterfield, the referee on Bacteriologic Methods for

Water Examination, was discussed by items. The following summary includes all recommendations discussed except editorial changes.

Recommendation—That the mouth end of all pipettes be protected with cotton plugs. *Approved.*

Recommendation—Increase in the temperature for sterilization of glassware. *Approved as follows:* The temperature should be 170° C., except where it is known by means of recording thermometers that the oven temperatures are uniform, under which exceptional condition 160° C., may be used.

Recommendation—Specification of Witte's peptone in place of Fairchild's. *Approved.*

Recommendation—Omission of the "drop-ratio method" for the determination of the pH. *Approved.* Buffer solutions should be checked with a potentiometer not less than once a year. If molds are present the buffer should not be used.

Recommendation—That the reaction for media be changed to a pH of 6.6 to 7.2 or 7.4. *Change approved to read:* 6.4 to 7.0.

Recommendation—In the preparation of nutrient agar to omit "cool to 45° C. . . without stirring." *Approved.*

The present formula for Endo medium was *approved* but it was suggested that an optional formula be given.

Recommendation—That "under no conditions should distilled water be used for dilution." *Approved.*

Recommendation—That the specification "Gram negative" be eliminated in the definition of organisms of the coli-aerogenes group. *Not approved.*

* See page 47 of this issue.

Recommendation—That only one typical colony required to be picked for the completed test. *Approved to read*: "one or more."

Recommendation—That the paragraph on the interpretation of results in the coli-aerogenes group be omitted or modified. Committee *approved* the *re-writing* of this paragraph.

Recommendation—That the section giving methods for differentiation of fecal from non-fecal members of the coli-aerogenes group be omitted. *Not approved*.

A majority of the committee was opposed, at the present time, to the inclusion of Brilliant Green Bile as a standard medium.

Changes in the following chemical methods were presented but action was withheld until the exact procedures could be formulated—manganese, rapid boiler water analysis, chemicals used in water purification, iodides, turbidity, phenols, settleable solids in sewage, total solids in sewage, fixed and volatile sulphides.

No report was received from the referee on Microscopic Methods.

It was agreed that some mention should be made of methods for the examination of swimming pool water.

It was tentatively agreed to change the method for the preparation of standard lactose broth so that after the ad-

dition of the portion of water the medium should be of the approximate composition now regarded as standard.

A complete report concerning the methods for reporting the numbers of coli-aerogenes group organisms will be prepared during the coming year.

It was voted to request permission from the Surgeon General of the U. S. Public Health Service to publish the report of the "Advisory Committee on Official Water Standards" as a supplement to the next edition of *Standard Methods of Water Analysis*.*

The following referees were appointed:

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Maternal Mortality in the United States—The maternal mortality rate for the United States is comparatively very high and has declined but slightly during the past decade. The Maternity and Infancy Act was passed in 1921. In that year, deaths of women from puerperal causes were 68 per 10,000 live births and in 1927 had declined to 65 per 10,000 live births. The decline was slightly greater in the rural than in the urban area. Puerperal septicemia accounted for 40 per cent of all puerperal deaths in the United States in 1927, the rate being 25 per 10,000 live births as compared with 16 for England and Wales and 19 for Scotland.

The U. S. Children's Bureau has begun an investigation of maternal deaths in 15 states in response to requests from state departments of health and state medical societies. A preliminary report has been made of the investigation of the 1927 maternal deaths for 7 of the states. There were 1,256 maternal deaths reported and 480 of these were due to puerperal septicemia. Abortions preceded 42 per cent of the deaths from septicemia and 87 of the 200 septic abortions were self induced. There were also 99 deaths in which abortion was a factor, or a total of 299 abortions for the 1,256 maternal deaths in the 7 states.

Reports were also made of the findings in Nebraska and Maryland for 1927. The infant mortality rate for Nebraska in 1927 was 51 per 10,000 live births. The maternal mortality rate was 59 per 10,000 live births in Nebraska in 1927 as compared with 65 for the whole birth registration area. The rate for the urban area was 92 per 10,

000 live births and 49 for the rural area. First pregnancies showed a maternal mortality rate of 71 per 10,000 live births as compared with 51 for later pregnancies. In Nebraska, less than one-half of the maternal deaths followed births of living children, more than one-fourth followed abortions and about one-seventh followed stillbirths. For Maryland, the infant mortality rate was 81 per 10,000 live births in 1927; 68 for white infants and 134 for negro. The maternal mortality rate for the white race in Maryland in 1927 was 54 per 10,000 live births and 72 for the negro. There were 187 maternal deaths reported and the results of the analysis for the white race in Maryland were very similar to those for Nebraska.—D. C. Mendenhall, *Med. J. & Rec.*, 130: 407-408 (Oct. 2), 1929.

Scarlet Fever—It is a well known fact that scarlet fever is a disease of temperate countries, being specially prevalent in the countries of the north and very rare in the tropics. There has been a recent increase of the disease in Europe, specially in Eastern Europe. In the U. S. S. R., the number of cases rose from 33,263 in 1921 to 75,718 in 1928. For some years, the prevalence of scarlet fever has been increasing in the United States. In 1925 there were 135,937 cases among a population of 86,571,000 in those states where the disease is notifiable; in 1926 there were 143,150 cases, and in 1927, 158,978 cases in a population of 90,482,000. For selected countries of Europe, America, Asia and Australia, a considerable increase has been observed since 1922, when there were 473,328 cases, the max-

imum having been reached in 1927, with 833,647 cases.

The scarlet fever case rate has shown a general tendency to diminish in Western Europe during the last 30 years. In Germany the decline was particularly marked between 1901 and 1917 and since then seems to have reached a stabilized level. The same applies to Belgium, France, Spain and Switzerland. The minimum case rate in the Scandinavian countries was reached after the great epidemics of the middle of the last century. In Italy, the scarlet fever case rate shows a tendency to stabilization though considerable fluctuations occur. On the other hand, in Eastern Europe the case rate is increasing. The rate for Czechoslovakia has increased from 31 per 100,000 in 1920 to 146 in 1928 and for U. S. S. R. from 129 in 1921 to 255 in 1928.

There is no doubt that the case mortality rate is at present decreasing in most countries of Western Europe. In 1928, the mortality rate in Germany was 0.9 per 100,000 as compared with 3.1 in 1921; the rate in England decreased from 1.2 in 1920 to 0.7 in 1927. A decline from 2.5 in 1920 to 1.1 in 1927 has been observed for the United States. In Eastern Europe, the mortality rate is still very high. In 1928 it was 5.4 in Roumania and 3.5 in Czechoslovakia.

Similar declines were shown for the scarlet fever death rates in the various countries. Thus, in Germany the death rate fell from 3.2 per 100,000 in 1920 to 1.7 in 1928, in England and Wales from 3.8 in 1920 to 1.5 in 1927 and in the United States from 4.6 in 1920 to 2.1 in 1927. Again the highest rates for 1928 were observed in Eastern Europe, Roumania having a rate of 4.8, and Czechoslovakia 5.5 per 100,000.

The fundamental causes for this general decline in the scarlet fever case rate and death rate are the mass immunity brought about by great epidemics dur-

ing the last century and the improvement in the living conditions of the poorer classes.—*Epidemiological Report of the Health Section of the League of Nations*, 8: 245-276 (July 15), 1929.

Results of Treatment of Diabetic Children—Prior to the discovery of insulin in 1922, diabetes in children was almost invariably fatal. Joslin treated 169 children who had diabetes from 1914 to 1922 and reported that one-third of them were still living at the end of the period. The experience at the Mayo Clinic was similar. From 1919 to 1922, 32 cases were treated and 21 deaths recorded. The survivors, 9 in number, benefited by insulin but 1 has since died. Thus, 70 per cent of the cases in the pre-insulin period resulted in death.

Insulin has changed the prognosis completely. In the first 6 years after its introduction, 167 children were treated at the Mayo Clinic, and a recent review of their progress showed that 147 were still living in 1928. They were all in good health except 3, 1 of whom had severe rickets and 2 who had unsatisfactory home care. There were 17 deaths in this series, a mortality of 10.4 per cent, which is a decided change from the pre-insulin mortality. In the last 3 years, about 4 per cent of the children have died.

Last year the annual mortality was 1.3 per cent, which is not much higher than the annual death rate for non-diabetic children. Of the 17 deaths, only 1 occurred at the clinic and this case was brought in moribund after 28 hours in coma. None of the other cases were under the immediate observation of the clinic; 8 had not been seen for from 6 months to 3 years. In 2 cases, death had occurred from influenza and encephalitis, diseases not related to diabetes. A third case died from meningitis but diabetic treatment had been neglected so that coma may have occurred termi-

nally. In all of the other cases, except 3 about which the information was incomplete, coma was the known cause of death and occurred from preventable causes such as failure to receive insulin, improper use of insulin along with carelessness in dieting and unsatisfactory medical supervision.—F. N. Allen, *Proc. Staff Meet. Mayo Clin.*, 4: 270-271 (Sept. 11), 1929.

Puerperal Septicemia in Massachusetts, 1928—This is a report of the committee appointed to study the incidence of puerperal septicemia in Massachusetts in 1928. The number of puerperal deaths reported for 1928 in Massachusetts was 456, and 123, or approximately 27 per cent, of these were due to puerperal septicemia. This is the lowest number of total puerperal deaths since 1912 and the lowest number of deaths from puerperal septicemia since 1916. Of the 123 deaths, 19 were due to puerperal septicemia in cases of abortion. The largest number of puerperal deaths were in March and the lowest number in September, and this seasonal distribution has been fairly constant over a period of a great many years.

From requests sent to physicians, 63 replies were obtained and 50 of these furnished sufficient data to use as a basis for this study. Primipara contributed 30 per cent of the deaths; para II, 32 per cent; and other multipara contributed from 2 to 12 per cent of the deaths. Of the 50 cases, 42 per cent died at home, 48 per cent in hospitals and 10 per cent did not report. There were normal deliveries in 54 per cent of the cases, instrumental in 6 per cent, 4 per cent were delivered by version, 2 per cent were undelivered, and 34 per cent did not report. Complications were present in 44 per cent of the deliveries and 28 per cent had no complications.

Adequate prenatal care was reported

in 64 per cent of the cases, doubtful care in 14 per cent, no care was received in 16 per cent, and 6 per cent of the cases did not report. Of the total number of cases reported, 6 per cent were autopsied and the autopsy confirmed the diagnosis of puerperal septicemia.

The highest birth rate, 26.4, in the state during 1928 was reported from Woburn, which did not report any cases of puerperal septicemia, but did report 2 deaths in the puerperal state. Waltham and Fitchburg, with birth rates of 24.2 and 20.4 respectively, each reported 2 puerperal deaths but neither from septicemia. Newburyport and Melrose, whose birth rates were 21.6 and 20.4 respectively, reported no puerperal deaths. Brookline, whose birth rate, 3.1, was the lowest, did not report any puerperal deaths. The city of Boston did not report any deaths from puerperal septicemia in November, 1928, and 1 each in September and December, 1928.—*New England J. Med.*, 201: 470-473 (Sept. 5), 1929.

Public Health in Kenya—A report of conditions in the Colony and Protectorate of Kenya states that according to a census taken in 1926, there were 12,529 Europeans, 30,583 Asiatics and 10,577 Arabs in the colony. The estimated African population in 1927 was 2,847,632. Local native health councils have taken an increasing interest in health matters. On the coast, useful measures are being taken against hookworm infestation. The country has been free from epidemics of serious diseases. Plague required watching but no serious outbreaks occurred during 1927.

Smallpox was introduced from India and caused some uneasiness because the cases were observed over a considerable area. The outbreak did not assume any magnitude, no doubt due to the wholesale vaccination campaign conducted two years ago. The epidemic of mala-

ria experienced in 1926 did not recur. Over 200,000 individuals were examined for trypanosomiasis, and only 380 cases were detected, these being found in well defined areas. In one small locality of about 800 population, over 100 cases were found. Progress for provisions of loan funds for hospitals has not been so rapid as was hoped, but one small hospital is practically completed.—*Lancet*, 217: 312 (Aug. 10), 1929.

Official Vital Statistics of Scotland—The Health Organization of the League of Nations has published a handbook which describes the procedure of gathering vital statistics in Scotland. For the purpose of local health administration, Scotland is divided into burghs, county districts and counties. In the Lowlands and along the seaboard, local health services are well equipped with modern facilities and are excellently administered. The Census Act of 1920 became a permanent measure. It empowers the authorities to ask for a census at 5-year intervals. Prior to this, a special act was passed for each decennial enumeration. The Registrar General directs the census and the enumerators are selected by local registrars.

Births of living children must be declared to the registrar within 21 days by either of the parents, the medical attendant or some other appropriate person. The registrar has the authority to require this declaration personally or in writing within 3 months after birth. All births must be allocated to the parish of habitual residence of the parents of the child. Stillbirths must be notified as such by the attending doctor to the public health authority but not to the registrar. The mother of an illegitimate child is primarily responsible for the declaration of the birth. Such a

child is legitimated by the subsequent marriage of the parents.

Deaths must be declared to the registrar by a relative of the deceased or other appropriate persons within 8 days. A medical certificate of the cause of death must be completed by the medical practitioner attending the person during his last illness. There is no specific procedure for transmitting these certificates to the registrar. The *International List of Causes of Death* as revised in 1920 has been in use since 1911. The Registrar General publishes an annual report that contains information relating to the mortality of the country.

There are 11 infectious diseases that are compulsorily notifiable, 6 more notifiable in certain areas only and 12 others optional. Notification must be made by the head of the family, medical attendant or other appropriate persons to the medical health officer of the area. Local authorities are required to provide proper and sufficient means for disinfection. Vaccination is compulsory and effective within 6 months of birth.

County, municipal and hospital bacteriological laboratories are established throughout Scotland. Special decennial supplements are published by the Registrar General and include all relevant statistical data such as occupational and infant mortality which appeared in the annual reports during the decennium. There are also published independent annual municipal reports prepared by the medical officers of health of the principal Scottish cities and burghs. Notable features of these reports are the results of special studies or investigations relating to diphtheria, puerperal mortality, cancer, infant mortality and similar special studies.—League of Nations: Health Organization, *Statistical Handbooks Series No. 13*, Geneva, 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

ILLINOIS MOBILE WATER AND SEWAGE LABORATORY

ANSELMO F. DAPPERT AND HARRY F. FERGUSON, F. A. P. H. A.

*Assistant Engineer and Chief Engineer,
Illinois Department of Public Health,
Springfield, Ill.*

A COMPLETELY equipped mobile water and sewage laboratory was placed in service during the summer of 1929 by the Sanitary Engineering Division of the Illinois Department of Public Health. This laboratory will be used in carrying out the work and duties of the Department of Public Health in connection with water supplies, sewage works and stream sanitation, and will coöperate with the Sanitary Water

Board established by an act of the 1929 legislature, of which board the Director of Public Health is chairman and the Chief Sanitary Engineer is technical secretary. The mobile unit will lead to more efficiency and economy in field analytical work and will make possible more complete analytical data than has been possible with previous field equipment.

The experience acquired by the Sani-

INTERIOR LOOKING TOWARD THE FRONT

tary Engineering Division in designing and operating a mobile milk laboratory, which was constructed and placed in service during 1927, proved very helpful in planning and equipping the mobile water and sewage laboratory. The mobile milk laboratory has proved so sturdy and satisfactory that the water and sewage laboratory was made substantially similar, with some additional refinements and the necessary changes in benches and equipment to make it suitable for the different kind of work.

By use of the mobile water and sewage laboratory the development and maintenance of public water works can be improved, especially the operation of water purification plants, so that waters will be more assuredly safe and, incidentally, more economical operation of some water purification plants will be possible. It will be especially valuable for studying and checking the operation, efficiency and effectiveness of sewage treatment works and for stream pollution surveys, in furthering the interests of stream sanitation and conservation.

Some analyses of sewage and polluted streams must be made in the field if they are to be fully representative and valuable.

It has been very difficult and sometimes impossible in the past to handle such field analytical work without a mobile laboratory. Taking into consideration quality and quantity of work the mobile unit will make more economical such analytical work than has been possible with ordinary automobiles and boxed laboratory equipment, and there will be a saving on shipment of sample containers to and from the main Sanitary Engineering Laboratories at Springfield. It is estimated that the saving in traveling and transportation expense ordinarily incurred in the investigation of water and sewage works and polluted streams, as conducted in the past, will nearly compensate for the investment and operation cost of the mobile laboratory, and at the same time make possible more effective and reliable work. The cost, fully equipped, was only about \$5,900.

Among the analyses and tests that can be made in the mobile laboratory will be odor, color, turbidity, ammonia nitrogen, nitrites, nitrates, alkalinity, acidity, pH, chloride, chlorine, iron, dissolved oxygen, oxygen consumed, biochemical oxygen demand, bacterial counts, *B. coli*, and microscopical examinations.

The mobile laboratory staff will generally comprise two sanitary engineers who have had experience in addition to technical school training on analyses of water and sewage. The water and sewage bacteriologists and chemists of the Sanitary Engineering Laboratories at Springfield will be available to advise with the sanitary engineers, and even to go into the field with the mobile laboratory when special investigations or studies require special bacteriological and chemical services.

The work that was scheduled for this mobile unit as soon as it was placed in the field, most of which was based upon requests from those that had heard that the unit was being provided, indicates that this unit will be in constant service. This might well be expected when it is realized that there are over 500 public water supplies and about 200 sewage treatment works in the state, and that many streams are now so polluted that they are threatening existing and future water supplies, destroying fish and other aquatic life, destroying cattle watering places, making unsafe and unusable important bathing and recreational water areas, and causing some nuisance from odors and appearance.

Although the extensive Illinois hard road system makes it possible for most of the mobile laboratory travel to be on excellent, even roads it was decided in planning the mobile milk laboratory in 1927 that the body should be of sturdy construction. This was again considered to be a wise plan and therefore a similar standard 21-passenger, street-car type, Dodge Brothers motor bus was

selected as giving sturdy construction at reasonable cost. It is expected that both the milk and the water and sewage mobile laboratories will last and render service many years. The operating and maintenance cost data which have been kept in detail for the mobile milk laboratory confirm this opinion. The only important changes made at the Dodge Brothers factory from the standard bus was the omission of the seats, the installation of shades and fine mesh bronze screens on all windows, and a second wiring system.

In place of the passenger seats, laboratory benches were installed by the Kewaunee Manufacturing Company. One bench is 12 and the other is 9 feet long, providing ample and convenient drawer and cabinet space of suitable size, arrangement, and construction to hold securely the necessary equipment and supplies. Racks for reagent bottles were built in the place usually occupied by advertising racks in automobile passenger buses. All woodwork is of quarter-sawn oak with a pleasing, durable silver-gray stain and wax finish, except bench tops, which are of narrow birch strips matched, glued and treated with a black acid-resistant stain. The bench tops have special spring construction to prevent warping. Special consideration was given by the manufacturers to the strain of travel in the design and construction of the laboratory furniture.

There are dual wiring circuits. One circuit supplies 6-volt current from either the regular motor-generator-battery electric system or a special rectifier and battery system to the regular ceiling lights, an electric fan, and heating elements in the incubators. The other circuit was designed for 110-volt current and serves additional ceiling lights, 12 service outlets and a bacterial plate counter in the bench top, 6 service outlets on the uprights between windows, electric fans, movable electric room heaters, and a heating element in the

INTERIOR LOOKING TOWARD THE REAR

37.5° incubator. The 110-volt circuit can be used when that current is available at the water or sewage plants or where the laboratory is stationed, and can easily and quickly be connected by means of a 100-foot reel of insulated wire and feed plug carried in one of the cupboards having a covered hand hole from it through the bus body to the outside.

A 20° incubator is placed at the end of one bench and a 37.5° incubator, a gasoline stove and a drying oven are mounted on one bench top. An autoclave, water still, gravity dilution water bottle and rack, necessary gasoline and alcohol torches, and all miscellaneous equipment and glassware affording the most modern laboratory facilities, are provided. All equipment and supplies are installed or stored so as to be easily available with minimum time and effort of handling between laboratory set-ups. Seven burette rods are screwed into fittings in one of the bench tops. The burette rods and also the electric service outlet plates and sink faucet are chromium plated.

Running water is available at a white enameled sink built in one of the bench tops. The water is stored in a 30-gallon tank suspended from the car frame below the laboratory floor. Water and air pipe connections extending through the bus body make easy the filling of the tank with water and applying air pressure through the tire valve on the air-line. This makes it possible to obtain water and air pressure at any gasoline-filling station. A metal tank, mounted under the laboratory floor, equipped with suitable piping and valve, serves to store the waste sink water when and where it is not desirable to discharge such waste water directly onto the ground.

A door at the right front and another at the rear of the center aisle with folding step afford ready access and also facilitate passage of persons through the bus when it is used for educational or exhibit purposes.

The aisle is wide and long enough to accommodate folding cots, providing bed space for two persons. The cots can be stored in one of the bench

compartments. These sleeping accommodations will be valuable especially when running 24-hour tests on sewage works or if the mobile unit at any time is called into special service following disasters such as tornadoes and floods.

The interior can be heated by two floor heaters located in the aisle and operating on the engine exhaust, in addition to the movable electric heaters that can be operated off the 110-volt current when available.

In addition to making it possible to comply with the increasing requests to the Department of Public Health and the newly organized Sanitary Water

Board, for water, sewage and stream analytical services, it is considered that the bringing of this mobile laboratory to water and sewage works throughout the state will serve to stimulate and bring about more and better local analytical control of such works, similar to the results obtained through the mobile milk laboratory visits to milk pasteurization plants. The Illinois Department of Public Health believes that this mobile water and sewage laboratory is equal in design and equipment to any operating in the United States and will be a factor in maintaining public health work in Illinois on a high scientific standard.

Changes in Composition of Gas during Digestion of Fresh Solids—The changes in the composition of the gas produced during the course of digestion of fresh solids were considerable. The CO_2 varied from 37.7 per cent during the first week to 25.3 per cent at the end. The methane content varied likewise from 47.8 to 69.8 per cent. For practical purposes 80–85 per cent of the total gas produced is the practical limit. If 10 per cent more gas is required, the digestion time must be increased by 25 per cent and to get all the gas the digestion time should be doubled. When 80–85 per cent of the gas has evolved the sludge is stable and has only a "gas odor" and drains well.—W. Rudolfs, *N. J. Agri. Exper. Sta. Bull.*, 486: 54–59, 1929. Abstr. W. Rudolfs.

was made whereby the City of Lawrence disposes of the sewage on payment of \$50 for each residence connected to the sewer system, and also on payments to reimburse the City of Lawrence for building and rebuilding certain main sewers within the city. Furthermore, all real estate within the sewer district is taxed to support the system at the same tax rate that prevails in the City of Lawrence for sewerage purposes. The district agrees to abide by whatever ordinances prevail in the city relating to exclusion of troublesome substances to the sewer and to plumbing restrictions.

Other notable examples of sanitation districts are mentioned, including the Los Angeles County Sanitation Districts and the Chicago Sanitary Districts.

The article states that the law that provides for the creation of the district contains "the basic elements of a most needed and useful instrument. The refining effects of protests, court actions, experience of use, and legislative amendments, are needed now to make it applicable to all cases that may arise."—E. F. Kindsvater, *Munic. News & Water Works*, 76, 7: 297–298 (July), 1929. Abstr. C. G. Gillespie.

Providing Sewer Facilities in Rural Communities—Chapter 165 of the Session Laws of Kansas, 1927, provides for installation of sewers and sewage disposal in rural and suburban communities. The application of the act to the Douglas County Sewer District No. 1, adjacent to the city of Lawrence, Kans., is described. In this case a contract

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Report on 1,000 Physical Examinations of Male Clerical Workers.

Conclusions—Complete physical examination of 1,000 white male office workers of ages 25 and under to 65 and over revealed that 781 possessed significant physical defects. Minor physical defects only were noted for 213 men. Those essentially free from physical defects numbered 6. In rank of numbers of examinees involved, defects of dentition, weight, vision, cardiovascular system and hearing in the order named were outstanding.

In view of the apparent causes predisposing to heart disease around 40 years, these findings are significant: Among 1,000 male office workers, 1.6 per cent had albuminuria and 1.9 per cent had glycosuria; hypertension was found for 12.9 per cent; and hypotension for 13 per cent; overweight was common to 42.3 per cent. Among all examinees the rate for cardiovascular defects was 36.1 per 100, but among those 20 lb. or more overweight the rate was 49.1 while among those 20 lb. or more underweight the rate was 32.8 per 100. It is also noteworthy that one-third of all cardiovascular defects were found in men under 45 years. Not to be overlooked were 5 per cent with heart murmurs and 12 per cent with definite heart enlargement.

In a large number of instances defects were discovered in this study which were leading to or eventually would lead to serious physical handicap. Such conditions were unknown to 724 men who possessed them, or at least they did not admit knowing of them. Finally, the

examination records of the whole group definitely indicated that 80.5 per cent would profit by early medical care.—William H. Muhlberg, Carey P. McCord, Floyd P. Allen, Special Paper (in mimeograph form), read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

History of Workmen's Compensation Laws Covering Occupational Diseases—Some light on the obstacles which have been met with in the attempt to draft, pass, and perfect workmen's compensation laws is obtained from a study of their development in various countries. The fact has to be borne in mind that the original purpose of compensation laws was to provide, promptly, adequate economic relief and medical care to workmen disabled because of, and in the course of their employment by injuries due to the nature of their work. The laws, therefore, proposed a scheme whereby expensive and discouraging delays might be eliminated and the adjustment reached without recourse to legal hair-splitting. The two earliest laws covering employers' liability for industrial accidents were passed by Switzerland in 1877 and Germany in 1883, and these provided for the inclusion of industrial diseases. Disability to work is the only manifestation of occupational injury which is compensable under the law and disability from disease often does not ensue for several months, sometimes for years. The greatest confusion has resulted from the attempt to hold the employer liable for ill health among his workmen which has

Copies available from Dr. Carey P. McCord, 34 West 7th Street, Cincinnati, O.

been "aggravated" by the nature of the work. The settlement of straight out-and-out occupational disease claims has become a minor portion of the question.

Most of the forms of workmen's compensation acts may be classified thus:

1. Laws which definitely include occupational diseases, either by a schedule naming the diseases, a schedule relating diseases to definite processes, or having no schedule of diseases or processes

2. Laws whose wording is such that diseases are compensable in the same manner as industrial accidents

3. Laws which definitely exclude diseases except those which result from an accidental injury

The paper then discusses the laws of the following countries as they relate to compensation matters, particularly in reference to industrial diseases: Switzerland, Germany, Austria-Hungary, France, Greece, Belgium, League of Nations, Union of Socialist Soviet Republics, Finland, Italy, Spain, Portugal, Serb, Croat, Slovenes Kingdom, Great Britain, British Dominions.

Concerning the United States the material is in the form of a table which shows that 4 states (Arkansas, Florida, Mississippi, and South Carolina) have no compensation laws, also one Canadian Province, Prince Edward Island; that 31 states, 2 Canadian provinces and 2 territories exclude occupational diseases from their compensation laws; that 3 states and the United States (civil employees), and 1 territory have laws which might be interpreted to include them; and that 9 states and the United States (longshoremen and harbor workers), and 2 territories, also 7 Canadian provinces, definitely extend compensation to occupational diseases.

The report concludes with a synopsis of the provisions for workmen's compensation laws in the various states in the United States; provisions for reporting occupational diseases, and suggestions for the future work of the committee.—Report of the Committee on

Standard Practices in the Problem of Compensation of Occupational Diseases, presented to the Industrial Hygiene Section of the American Public Health Association at the Minneapolis meeting, October 4, 1929, 40 pp., 1 table.—Dr. A. J. Lanza, *Chairman*, c/o Metropolitan Life Insurance Company, New York, N. Y.

Tentative List of State Regulations, Orders, Advisory Pamphlets and Labor Laws Relating to Safety in Industry (arranged by states of the United States)—Library, National Bureau of Casualty and Surety Underwriters, 1 Park Avenue, New York, N. Y.—18 pp. mimeographed Nov., 1929.

The Health of Workers in Dusty Trades. II. Exposure to Silicious Dust (Granite Industry)—A few years ago, the U. S. Public Health Service began a series of intensive studies on the health of workers in dusty trades. The first study was reported in 1928, and dealt with the health of workers in a cement plant. The report on the second study, dealing with the health of workers exposed to silica dust in the granite cutting industry, has recently been published. The study was of such a character as to present a rather definite picture of what happens to men working for many years under a dust hazard of the extent described. The salient points may be summarized as follows:

- a. The long period of service before the liability to tuberculosis becomes manifest (generally 20 years or more)

- b. The sharp correlation between length of exposure to the dust and the prevalence of tuberculosis and also the death rate from this disease

- c. The close relation between the extent of dust exposure and health of the men

- d. The universal occurrence of silicosis among the workers

- e. The large proportion of workers finally succumbing to tuberculosis

- f. The almost invariably fatal form of the

disease within a short time after the onset

g. The different character of silicosis as manifested by X-rays compared with that shown where there is exposure to a dust with a much higher content of free silica

h. The location of the tuberculosis lesion, usually basal, where the disease complicates silicosis

i. The absence of deaths from silicosis *per se*, tuberculosis apparently always intervening

j. The failure of workers to recover from their condition upon going into non-dusty trades

k. The high incidence of sickness of a severe nature from causes other than tuberculosis

l. The rising sickness and mortality rates from tuberculosis due to longer use of the hand-pneumatic tool

m. The high death rates at the present time from tuberculosis, compared with normal industrial experience

X-rays, micro-photographs of the lungs, detailed histories of cases, discussions and statistical findings accompany.—*Pub. Health Bull.* 137, 1929, 209 pp.

Industrial Dental Service—A study of physical defects in a group of 16,000 individuals, published in 1925 by Dublin, Fisk, and Kopf, showed that over 8 per cent had decayed teeth or infected roots; over 15 per cent infected gums or pyorrhea; and almost 42 per cent heavy dentistry which warranted X-ray examination. Above all does the average individual need frequent counsel and guidance regarding his teeth.

In an organization of 1,000 employees, a single chair, a part-time dentist, and a full-time hygienist may be sufficient to do prophylactic work, extractions, and minor filling operations—clerical assistance should not be overlooked. The cost of chair, including cuspidor and engine, and of instruments is about \$1,500. X-ray equipment would approximate an additional \$800. Proper record forms should be used (and samples of these are exhibited).

In the experiment of the Metropolitan Life Insurance Company in which 1,000

good mouth conditions were compared with 1,000 poor mouth conditions, the following diseases or conditions were all more pronounced (in some cases triply so) in the case of the latter: neuralgia and neuritis, headache, nervousness, colds, furuncles, abscesses, and albuminuria. A brief discussion is given of the dental service conducted by the Metropolitan Life Insurance Company; the United Railways & Electric Co., Baltimore, Md.; the Sullivan Machinery Company, Claremont, N. H.; the National Lamp Works, General Electric Company, Cleveland, O.; Jordan Marsh Company, Boston, Mass.; Corning Glass Works, Corning, N. Y.; the Union Health Center Dental Clinic, New York, N. Y.; and the Hood Rubber Company, Watertown, Mass. The most extensive of these appears to be that of the Union Health Center Dental Clinic, which is conducted by the New York locals of the International Ladies' Garment Workers' Union, whose work in 1927 included 9,338 X-rays, 11,548 prophylaxes, 2,575 general treatments, and 16,709 other treatments—making an average of 625 patients per day, the charges ranging from \$4.00 to \$5.00 an hour and cost of materials. (The article gives a list of the 12 institutions where dental hygienists are trained and a list of some 90 companies which have industrial dental dispensaries in the United States and Canada.)—Metropolitan Life Insurance Company, Special Pamphlet, *Industrial Dental Service*, Ill., *Industrial Health Series No. 3*, 1929, 31 pp.

Industrial Disease Investigation Bureau—The bureau began operating January 1, 1929, and reports for the period to June 30, 1929. It employs a field director, a medical director, a technician and laboratory expert, a consulting chemist, and a consulting pathologist.

The New Jersey State Law provides

for compensation for: anthrax; poisoning by lead, mercury, arsenic, phosphorus, wood alcohol, and chrome, benzene and its homologues, and all derivatives thereof; caisson disease; and mesothorium or radium necrosis.

Under "Investigation," 29 plants were covered, 10 using benzene or its derivatives (dyes, perfumes, chemicals, and artificial leather—despite the fact that the Department of Labor has recommended that benzene be eliminated in industry due to its poisonous qualities, in which most plants have concurred); 11 using lead and its products (smelters, making of reflectors, storage batteries, chemicals, pottery, colors, and tetra-ethyl lead); 7 using mercury (hat factories, chemicals, thermometers, and storage batteries), and 1 using chrome. It was quite evident that chronic mercurial poisoning still exists in hat factories since tremors (shakes) were common in a large proportion of the men seen in the shops.

Physical examinations in plants covered 89 workers exposed to benzol (10 showing strongly suggestive symptoms), and 21 exposed to lead (8 found to be suffering from active lead absorption despite the fact that they were wearing respirators).

Concerted effort has been made to spread knowledge of occupational diseases among physicians, employers and employees, both concerning occupational diseases and the special clinic set up for their investigation in Newark. This clinic provides free laboratory work and other diagnostic facilities, and makes diagnoses which are available to the family physician, but no treatment is attempted. A museum is contemplated. An accompanying table shows that for the first 6 months of 1929, 184 patients were examined at the clinic, 321 tests made, 230 blood counts, 11 urinalyses, 5 tests for lead in urine, 1 test for lead in the feces, 2 for blood Wassermanns, 13 tests for mercury in urine, and 59 tests

for coagulation and bleeding time. These concerned 106 patients exposed to benzene, 27 to lead, 14 to mercury, 1 with phosphorus and 6 undiagnosed. In addition services were offered non-occupational cases at the Newark City Hospital, involving 36 patients suffering from various blood diseases, like pernicious anemias, malaria, leukemia, etc., with corresponding tests, blood counts, etc.

In summary: 24 plants were visited for inspection of processes, etc.; 122 workmen were examined in 4 plants for lead and benzol; while Dr. Henry H. Kessler, the Medical Director, made 203 physical examinations.

On page 33 of the *Bulletin* is a table of 99 poisonous and 274 corrosive substances and 150 occupational diseases, by causes, which were compensated in 1928. Under "occupational" are included certain poisons, compressed air, dust, infections, heat and light, and activity (cellulitis, etc.).—Joint Report of the Industrial Disease Investigation Bureau, New Jersey Department of Labor, *Indust. Bull.*, 3, 9: 11-15 (Sept.), 1929.

Some Physiologic Reactions to Cooling Power during Work—With Special Reference to Evaporation of Water—Among other points the authors point out that removal of clothes during work reduced evaporation from the skin and so did wind. In moist and moving air at 10°, 15°, and 20° C., the amount from the skin was often nearly nil. It is suggested therefore that greater use should be made of the removal of clothing and movement of air to render conditions comfortable for indoor muscular workers.—J. Argyll Campbell and T. C. Angus, *J. Indust. Hyg.*, 11: 315-327 (Nov.), 1929.

Effect of Carrying Loads—Curvature of the spine, as well as inguinal hernia and flat feet, has been observed among persons employed in carrying

loads. Steinmann of Berne and Waeger of Moscow state that under certain circumstances a shock or a false step is sufficient to overcome the resistance of the spinal column of a worker carrying a load, which may injure the whole column or the most exposed vertebra. This occupation shows high statistics of accidents, a considerable proportion of which affect the spine. The risk of disease varies directly with the size of the load; consequently, legal regulation of the weight of loads would mark an important advance in the prevention of accidents and occupational diseases of the type described. The International Labour Organization is called upon to draft an international Convention fixing the maximum weight of loads to be carried at 75 kilograms (165 lbs.).—*Industrial and Labour Information*, International Labour Office, Geneva, XXIX, II: 334–335 (Mar. 18), 1929.

The Problem of Displaced Workers—

1. Workers dispossessed by the introduction of labor saving machinery and the rationalization of industries do not easily find new employment, as 45 per cent of 754 workers in Baltimore, Md., Chicago, Ill., and Worcester, Mass., had not found employment when seen by investigators.

2. Of those who found new employment, more than one-half had been idle for more than 3 months.

3. Less than 10 per cent of those surveyed were reemployed at their old jobs; two-thirds went into entirely different industries.

4. Only about 15 per cent went into the rapidly growing "newer" industries and service trades.

5. About one-half of those finding new jobs succeeded in getting tasks which were similar to those formerly held.

6. A large majority of dispossessed workers supported themselves and families during the early period of unemployment by accumulated savings. Approximately one-third found temporary work.

7. Transition from one job to another was in most cases made with a sacrifice of income, as almost one-half took new jobs at

lower wages, while 18 per cent benefitted by the change, and one-third experienced no change of income.

8. The age of the worker appears to be a significant factor in securing new work, as relatively fewer of those over 45 years of age were able to secure new jobs as compared with the younger workers, and they were out of work for longer periods at a time.

In order to deal with this form of unemployment a greater perfection in employment exchange system is needed and some form of unemployment insurance is urgently required, but the government's participation in the latter is considered neither necessary, nor advisable at the present time.—Institute of Economics, Brookings Institute, Washington, D. C., *Industrial and Labour Information*, XXXI, II: 344–346 (Sept. 9), 1929.

Status of Industrial Safety Regulations—In an effort to obtain a statement as to the specific safety codes or regulations in force on January 1, 1928, in the various states, the U. S. Bureau of Labor Statistics communicated with each state and received replies from all except two. It is impossible to present a summary of the information obtained by the U. S. Bureau of Labor Statistics. Suffice it to say that an excellent digest is presented showing the status of safety codes in the various states. Those interested in obtaining information as to the status of safety codes throughout the United States are referred to this paper for an excellent summary of the subject.—U. S. Dept. Labor, *Month. Labor Rev.*, 28, 3: 521 (Mar.), 1929. L. G.

How Chemistry has changed Industry, and as a result has changed the Tendency to Occupational Disease—G. D. Gehrmann, Medical Director E. I. du Pont de Nemours & Co. U. S. Bureau of Labor Statistics, *Bull. No. 485*, 125–129 (June), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Nutritive Value of Proteins in Certain Kinds of Sausage and Other Meat Food Products—The importance of sausage is emphasized by the fact that sausage and sausage casings in the amount of more than $1\frac{1}{2}$ billion lb. were manufactured in the United States in 1925 exclusive of that made by small dealers and farmers.

Sausage as defined by the U. S. Department of Agriculture is made from meat and meat by-products obtained from cattle, sheep, swine and goats, the meat obtained chiefly from trimmings of swine and cattle carcasses; condiments are used, and a small amount (not more than 3.5 per cent) of cereal may be added.

Previous investigations by the authors have shown considerable difference in protein values in the meat and meat by-products and this work was undertaken to compare the nutritive value of the different types of sausage and meat food products. Six different types of sausage were studied in addition to headcheese, scrapple and meat loaf, and for purposes of comparison fresh pork ham and beef chuck, all obtained from federal meat inspected establishments. Descriptions of the different types of sausage and the meat food products are given.

Young male albino rats were fed the various rations for 60 days; the animals being weighed twice weekly and records kept of the food consumed. Protein was fed at a 10 per cent level and the meats were supplemented by essential dietary factors including mineral salts. Complete tables are given showing the feeding experiments for both the 30- and 60-day periods.

For comparison, meat food products were divided into three groups—first, those of the highest nutritive value, pork sausage, Braunschweiger-style sausage, and meat loaf; second, intermediate values, Frankfurter-style sausage and Bologna-style sausage, and scrapple from one manufacturer; third, the low nutritive values, liver sausage, headcheese, and fresh link sausage, and a sample of scrapple. In the first group, the gain in weight per gm. of protein consumed is from 3.08 (pork sausage) to 3.47 (meat loaf), compared to 2.93 gm. to 3.68 gm. beef chuck and fresh ham. In the second group, gains per gm. are from 2.34 (Frankfurter-style sausage) to 2.87 (scrapple), and in the third group corresponding gains were 1.58 (headcheese) to 2.25 (liver sausage).

At the end of the 60-day period the groups were rearranged, first, including pork sausage, Braunschweiger-style sausage, meat loaf, Frankfurter-style sausage and one sample each of Bologna-style sausage and scrapple; second, one sample each Frankfurter-style sausage and Bologna-style sausage, and the third included headcheese, fresh link sausage, liver sausage and one sample of scrapple.

Weight gains per gm. protein were: Group 1, 2.41 (Braunschweiger-style sausage) to 2.73 (pork sausage) compared to 2.32 (beef chuck) to 2.75 (pork hams); group 2, the range is 1.96 to 2.30 (Bologna-style sausage), and group 3, 1.51 (headcheese) to 1.95 (fresh link sausage). The material differences in nutritive values warranting the classification into groups apply to the samples tested and not generally.

Two lots of scrapple showed a difference in gains of 1.77 and 2.52 respectively, due probably to the greater proportion of lean meat in the second sample which compares favorably with beef chuck and is attributed to the supplemental relationship between meat proteins and those of corn meal.—Ralph Hoagland and George G. Snider, *J. Agri. Res.*, 39: 531 (Oct.), 1929.

The Pellagra-Preventive Action of Canned Salmon—Previous observations have been recorded on the black-tongue-preventive action of canned salmon in the dog (Abstr., *A. J. P. H.*, 18: 1183 (Sept.), 1928). Evidence that canine blacktongue is analogous to human pellagra led to the comparative study of canned salmon on pellagra patients in the Georgia State Sanitarium, Milledgeville, Ga. A total of 18 white female patients were under observation and were treated with this diet for a period of 1 year or more. Alaska chum salmon was used and the entire contents of the can were incorporated in the cooked vegetable portion of the diet.

Six ounces of salmon per patient per day were fed. No patient in the group at any time during the test showed symptoms of pellagra, which warrants the conclusion that canned salmon contains the pellagra preventive factor. This is further evidence of the analogy between human pellagra and black-tongue in dogs.—Joseph Goldberger and G. A. Wheeler, *Pub. Health Rep.*, 44: 2769 (Nov. 15), 1929.

Do Baking Powder Residues Exert Injurious Effects upon Growth and Nutrition?—References are made to the conflicting statements in the literature particularly by recent investigators on the effects of compounds of aluminum on the human organism. References are also given as to the adverse effect of tartrates. On account of this uncertainty the authors have under-

taken this work to determine the possible injurious effects of certain baking powder constituents.

Three different types of baking powder were studied—those in which the acid reacting agents were (1) a tartrate, (2) calcium acid phosphate, and (3) calcium acid phosphate and sodium aluminum sulphate.

Young rats in 4 groups were placed on a diet complete in dietary factors and varied only in respect to the addition of the baking powder ingredients in 3 groups, the fourth serving as a control.

The powders added conformed as closely as possible with the manufacturer's directions, corresponding correction being made for the food materials used. Carefully mixed ingredients were made into a dough, rolled thin and baked at a temperature of 230° C. The bread was readily consumed by the rats and given *ad libitum* with the addition of 20 gm. head lettuce per rat every 4 days. At the end of 220 days certain animals were bred and the young at weaning were put on identical diet except that in each group the proportion of baking powder to food was doubled. At the end of the feeding test both generations were killed, blood analyzed for non-protein nitrogen; kidneys were weighed and examined histologically.

Complete tables are given for both generations as well as graphs showing the growth curves. Food consumption was relatively high but kidney weights indicated no hypertrophy. Microscopical examination of kidneys showed no difference between the controls and those on the baking powder diets. No differences were noted between the non-protein nitrogen of the blood except in one isolated individual. Growth curves for all series show normal gain in weight except that those on the phosphate powder gained slightly less than the rats of the corresponding sex on the other three rations, but the difference is insignificant. Even more rapid growth was

noted in rats of the second generation consuming twice the amount of baking powder.

Compared to a 70 kilo man the amount of powder ingested by the rats would approximate 42 gm. P_2O_5 in the phosphate powder, 8.9 gm. P_2O_5 and 2.5 gm. Al in the phosphate and aluminum powder and 30 gm. of tartaric acid in the tartrate powder. In this connection it is noted that the largest dose of aluminum employed by the Reference Board was 1 gm. per day.

Reference is made to the report of Schaeffer, *et al.*, *Bull. Soc. Sci. d'Hyg. Alim.*, XVI, 1928, on a sodium aluminum sulphate and calcium acid phosphate baking powder attributing to the ingestion of this ingredient such effects as gastric evacuation, intestinal ulceration, diarrhea, and inhibition in growth.

The report also stated that rats less than 90 gm. weight were not resistant to the baking powder, but in the present work most of the rats were under 65 gm. when the diets began.

Discrepancies are attributable to excessive amounts of baking powder used by Schaeffer, one diet containing 15 per cent, since a similar proportion of necessary dietary factor such as salt might produce untoward results. The conclusion is reached that with the types of baking powder employed and in the proportions stated there is no evidence of any deleterious effects whatsoever on the experimental animals and that they are comparable in every way to the control

rats.—William A. Rose and Florence L. Catherwood, *J. Nutrition*, 11: 155 (Nov.), 1929.

Vitamin A Content of the Green and White Leaves of Market Head Lettuce—It has been previously shown (*A. J. P. H.*, 17: 1193 (Nov.), 1927) that the vitamin A content of head and leaf lettuce varied with the greenness of the leaves. The experiment here reported was undertaken to show the degree of differences in vitamin A content in outer green leaves and inner white leaves.

California head lettuce of the Iceberg variety, purchased in a market in Kansas, was used. Only leaves which were totally unfit for human consumption were discarded, and the heads were wrapped in damp cloths and kept in a refrigerator.

Albino rats, 4 weeks old and of similar weights, were used. When the stored vitamin A was depleted, the animals were given, in addition to the vitamin A-free diet, weighed amounts of inner white leaves and of outer green leaves and growth was observed for 8 weeks.

It was found that the green outer leaves of head lettuce contained 30 or more times as much vitamin A as equal weights of the white leaves, the unit for the dark leaves being between 0.015 and 0.02 gm., and for the white, 0.6 gm.—Martha M. Kramer, Gladys Boehm, and Ruth Esther Williams, *J. Home Econ.*, 21: 679 (Sept.), 1929.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Qualifications for Industrial Nurses—Florence Swift Wright, R.N., has written *Industrial Nursing*, a book which is a classic in this specialized field of public health nursing; yet of 15 industrial nurses who gathered at a dinner in a middle western city a short time ago, not one had ever heard of the book.

As Miss Wright says, most industrial nurses enter the plants of their employers by way of the first aid rooms. There are still some school nurses who do nothing but first aid work, but the school authorities are fast learning that first aid is only one of the ways in which the school nurse finds opportunities for service; and the time is coming when industrial concerns will find that the value of the industrial nurse to both employer and employee steadily increases as she enters the field of prevention.

The New York State *Health News* for October 21, 1929, states that at the New York State Annual Conference of Health Officers and Public Health Nurses, Grace M. Heidel, Supervisory Nurse for the New York Central Railroad lines, drew up some conclusions regarding the qualifications for nurses doing public health work in industry. They are:

1. Minimum course in public health nursing with practical field work, if possible (4 months at one of the universities giving an approved course in public health nursing, or 8 months on the staff of a public health nursing association under good supervision is the minimum standard set by the National Organization for Public Health Nursing).

2. Understanding of the principles of social service and mental hygiene.

The young nurses just out of training,

to say nothing of the practical nurses many industries consider satisfactory, have had no chance to acquire these minimum qualifications for their positions. Of 26 industrial nurses present at the meeting where Miss Heidel spoke, only 2 had had any training in public health, and only 3 had done any visiting nursing. Two were not even registered nurses.

Despite the fact that there are wide fields in the ranks of industry for public health nurses to teach the workers how to care for their own health, these opportunities are almost everywhere apparently being lost, either because the industrial nurses themselves do not see what is lacking or because the employer has never been shown what a real preventive program carried out by a real public health nurse could do for his plant.—Florence Swift Wright, *Industrial Nursing*, 1928, p. 7. *Health News*, New York State Department of Health, Qualifications for Industrial Nursing, 167 (Oct. 1), 1929.

The Passing of Anna McGee—a Pioneer Public Health Nurse—Public health nursing is such a comparatively new profession that it has not many outstanding older nurses among its ranks. One of them was the late Anna McGee of Schenectady, N. Y., who at the time of her death on October 28 was Director of the Schenectady County Public Health Nursing Association.

Dr. Julius Tandler, Health Commissioner of Vienna, Austria, who gave an address at the International Congress of Nurses in Montreal this summer, remarked that if he had his life to live over again he would like to be an Amer-

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

ican public health nurse because of the romance and human interest of her work. This is well borne out in the life of Miss McGee, which must have been full of romance and adventure.

She was doing private duty nursing when she made the acquaintance of Theodore Roosevelt, who was organizing his regiment for the Spanish-American War. She volunteered her services, and was the first woman to enlist for foreign service. Later, President McKinley put her in charge of the American hospital in the Philippines. She was assigned to duty under Admiral Dewey and was on his flagship, the *Olympic*, when the vessel steamed into the harbor of Manila.

She was transferred to Cuba where she did duty on the battlefield at San Juan Hill.

Soon after she returned to the United States she was assigned for duty with the Ninth Infantry, which was ordered to China to quell the Boxer uprising.

Returning to the United States she joined with Lillian Wald, the founder of the Henry Street Settlement Nursing Service in New York City.

During the World War her services were very valuable in the recruiting of nursing forces for service in this country and in France.

She was always an ardent Red Cross worker in her local chapter. She was an active worker in the Schenectady Federation of Women's Clubs, and was chairman of the public health nursing committee of the New York State Federation of Women's Clubs.

Miss McGee was a charter member of the National Organization for Public Health Nursing, and was affiliated with the Public Health Nursing Section of the A. P. H. A.

She Is a Teacher-Nurse—It seems difficult for a great many people to understand the work of the public health nurse unless they have had some vital contact with it or been very closely as-

sociated with it over a period of time. Some feel that public health nurses are not graduate nurses because they wear blue or gray instead of white uniforms. One college student whose instructor took his class to visit the office of the local public health nursing association, exclaimed afterwards to the instructor, "I'm so glad you took us down there. I have often seen those nurses on the street, but I always thought they were nuns."

In the November, 1929, issue of *The Survey*, Dorothy Deming describes the work of a public health nurse in a way that entertains while it informs.

In answer to the query, "What's public and what's healthy about a public health nurse?" from a young friend just recuperating from a tonsillectomy, who had for the first time that morning received the ministrations of a public health nurse in her home, the friend who had stepped in for an afternoon call and who had recommended a visiting nurse answered:

The public health nurse is a teacher and nurse, with a nicely balanced ability to do one or the other as the situation demands. If Mrs. Hardemup has broken her ankle and needs the skilled care of a graduate nurse only once a day, she calls for the nurse and scarcely gets a glimpse of the teacher. On the other hand, if Mrs. Poormother doesn't know how to launder her new baby, the teacher section of the nurse appears, and she gets a lesson in baby bathing. Most of the time the public health nurse isn't conscious herself which ability she is using, nor is her patient. It's just one big inseparable job.

In answer to the girl's complaint that her nurse that morning had not taught her a thing, the visitor explained:

She taught you how to read your clinical thermometer. . . . She fixed your light for night reading in a way you have never thought of. She wrapped your icebag so it wouldn't drip on your pillow, left a list of foods you can eat, wrote out that recipe for milk whip, explained why your ears hurt, and you never knew she taught you a thing.

The girl was beginning to get an

inkling of how the nurse did her teaching, but the visitor went on:

Now picture that same nurse in the home of a poor tenement family. The mother knows about six words of English. Two of the eight children have influenza. The father coughs constantly and is out of work. There are no medical supplies in the house, not even a quarter for the gas meter—does

she have to know how to teach? Add to her home visiting, assistance at clinics, conferences, mothers' clubs, school nursing, nursing in industries, a few talents on the side, such as poster making, public speaking, committee management, automobile hygiene—and you have a nursing job *plus*.—

Dorothy Deming, *Nursing by Leg Power*, *Survey*, Nov., 1929, p. 205.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

The Strange Case of Mr. Smith—
The reactions of "one who should know" are reported by B. K. Richardson, Illinois Department of Public Health:

Apropos of the diagnosis of the Strange Case of Mr. Smith at the Minneapolis Publicity Clinic. I placed a copy of this little booklet in the hands of my 8 year old boy. He read it through with apparent interest. His comment when he had finished it was "A bath would help, wouldn't it?" Then he wanted to know what the Joneses thought of getting Smith's cold.

Will You Help East Orange?—
And what do you do with the public waiting room?

In the new Health Building recently occupied by the East Orange Health Department, we have provided what is known as a public information room. Here, most persons visiting the department will stop for directions or will wait while the information they wish is being secured. In other words, it will be a public waiting room, and it is our purpose to make it work and to be instructive as well.

Among other things we have a universal display standard with 30" x 40" panels for posters, charts, maps and other educational material. I would greatly appreciate suggestions from you as to just what to use and how to obtain it. It occurred to me that

some readers might help us to dress up these panels with practical public health educational material.—F. J. Osborne, Health Officer, East Orange, N. J.

January 22, 1930—This is the date when Chairman John Sundwall will meet the Public Health Education Section Council in New York. The docket will include the Fort Worth program and other Section interests.

Recognition of Good Work Done—
Why should not health publicity claim one or more of the Harmon awards for the best records of a year's publicity? Making up the record should be good fun! And probably we will agree that such a record should be made anyway. Why not make up a duplicate set—for staff and board and publicity committee to study? Then permit the exhibition of one set at Fort Worth next October. The Harmon Foundation, 140 Nassau St., New York, will send you details.

What Might Have Happened!—

I almost had a heart attack when I failed to find your department in the August issue *A. J. P. H.* So when this month's issue arrived I looked for it first thing and heaved a sigh of relief.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Please let me criticise now that I've thrown my bouquet. You have two and one-half pages of material in that issue. Why leave the precious half-page blank?—B. P. R.

Answer: Sometimes because the next month comes too soon; sometimes because the editor at 370 cannot easily fit the copy into the space. But it was good to learn that one man noted the omission of this department.

Make Friends with Your Public—
Says J. Mace Address, Ph.D., in December, 1929, *Hygeia*, under "Health and the School":

A health program cannot hope to succeed unless it is looked upon in a friendly way by the rank and file of teachers. . . . A health program cannot hope to succeed unless it is regarded favorably by the general public. . . . There are also the parents. Their support is indispensable in the carrying on of the health program.

Then follow suggestions on relations with community leaders, parents and newspapers:

One of the striking measures in the child health demonstration at Fargo was the care with which the general public was informed as to the prospective health program and the spirit of civic coöperation that was aroused. From that point of view alone the report of the demonstration is worth reading with care.

Who Is Right? Who Says So?—
Taking pity upon the public, *Hygeia* (Dec., 1929) says:

If a distinguished scientist even suspects that he has found, for example, a cure for cancer, that is big news. It gets a lot of space and a good headline. Perhaps the professor was unwise in letting his suspicions reach the press, but we cannot censure the press for making a big story of it. It is the biggest story waiting to be told in the realm of modern medicine. A few months later, the scientist finds that he has not come to a correct conclusion. This is not such big news, and though duly reported, it is often overlooked by the reader. We may perhaps wish that the truth might catch up with the error, but that is seldom the case in any field of human relationship.

Moreover, the real newspaper in its news columns is telling you what happened, not what it thinks about the event. If the professor says so and so, the paper reports it. When speeches are made at conventions or other gatherings, the press reports them if they are interesting or the man who makes them is important. It does not distinguish between sources; it may report in the same issue the statements, often widely at variance, of physicians, leaders of faith-healing movements, anti-vivisectionists and representatives of this or that cult that claims to deal with health. It is all news; you must do the sifting. The question to ask yourself is—Who says so? . . ."

Then Dr. W. W. Bauer, in "Who Says So—Health Educators or Health Racketeers?" describes the sources of reliable health information. Good material for further use. A second chapter in the January, 1930, issue.

Who Uses Them?—Bookmarks, bookplates, book covers—in schools or elsewhere? Do you issue your own, or do you purchase them ready-made, or secure them free from an advertiser of a health product? Replies will be passed on, and samples will be displayed at Boston and Fort Worth.

The Alabama Movable School—
It consists of a large covered motor truck, operating out of Tuskegee Institute and carrying a crew of from four to six people, among whom are a federal farm demonstrator, two public health nurses, a home economics worker and the chauffeur. Possibly one or two others are also taken along for certain localities. All of the crew are colored. The county health officer or the county farm demonstrator or home bureau agent is notified in advance about the coming of the School. The truck drives up at a certain time in front of a farm which has been set aside for the purpose. Usually from 150 to 175 Negroes from the neighborhood are present. The male members of the School take the men out on the farm and go over it,

showing them how to prune trees, plant cotton, grow better stock, etc. The women from the School take the wives of the farmers and teach them how to cook, how to sew and how to make their homes look better. From the public health angle they teach them how to keep themselves and their families healthy. For example, they teach them how to take care of the baby, how to cook the food and how to take care of tuberculosis patients or others that are sick, etc., etc.

During the course of the demonstration the whole house and yard are cleaned up, whitewashed and a complete transformation is made during the day. The next day the School moves on to another locality and repeats its demonstration. In this way the people are taught health and farm economics right on the ground. On Sundays the School puts up at some place where there is a church and usually the service is given over to health. As many as 700 people are reached in this way on a single Sunday.

The School carries material for graphically demonstrating the points they wish to make and everything is presented in a manner that will be effective and will reach the Negro farmer to whom they appeal.

The enterprise is supported jointly by the Tuskegee Institute, Alabama State Department of Health, U. S. Bureau of Agriculture and the Alabama Tuberculosis Association.—Philip P. Jacobs.

The School will be demonstrated at the National Tuberculosis Association convention at Memphis in May, 1930.

DIPHTHERIA

The Search for the Unprotected Child in Chautauqua County (without name of agency or city address). Two pages of "Some Endorsements from Chautauqua County People."

Small 4-page folder—Knock Out Diphtheria. Cover page: photograph,

white on black, with black on white silhouette—different, effective. Inside: white on black photograph, with conversational text. Racine Health Department. Better send 2 cents for copy.

Philadelphia's 1929 diphtheria campaign described in *Monthly Bulletin*, Department of Public Health, Philadelphia, Pa. Among the publicity features were a series of six announcements, each about 100 words in length, given by several radio stations during the 10 days of the campaign; free advertising space in several dailies; 1,000 large red and blue posters distributed by a motion picture company; free advertisements in motion picture programs for a week.

READING REFERENCES

Eighty-five references to books, chapters and articles are given in *Supplement to Publicity Methods Reading List*, under such headings as: The Public and Public Opinion, Copy, Exhibits, Financial Campaigns, House Organs, Lists, Mail, Meetings, Motion Pictures, Newspapers, Plays and Pageants, Posters, Printing, Public Speaking—and publicity in special fields, including Public Health.

The 1924 edition includes 48 pages of references listed under 29 headings. Both for 30 cents. *Copy of the Supplement free upon request by all who already have copies of the 1924 edition.* Russell Sage Foundation, 130 E. 22d St., New York, N. Y.

WORDS—"HUMANIZED"

The *London Mercury*, speaking of the new *Encyclopedia Britannica*, which had to be "humanized" to meet the requirements of the large mass distribution in the United States:

... and "humanized" in a very large proportion of the work—and that not the least scholarly—has simply meant plain English, and a merciful brevity, and a few explanatory words now and then to help the ordinary reader over some style.

SLOGANS AND PHRASES

"Knock out diphtheria"—Racine Board of Health.

"Protect them from tuberculosis" (with child picture)—Early Diagnosis Campaign, 1930.

"Spare the sweets and save the teeth"—Extension Division, University of Iowa.

HONORABLE MENTION

To Department of Health, Morristown, N. J., for table of contents in annual report.

To *Missouri Public Health News*, State Board of Health, Jefferson City, Mo., for table of contents.

To Board of Health, East Orange, N. J., for table of contents in annual report.

To Marion County Tuberculosis Association, Indianapolis, Ind., for title of annual report—"Progress in Public Health in Indianapolis and Marion County."

To Public Welfare Commissioner, Philippine Islands: for table of contents in annual report (plus heavy demerit for mailing report rolled).

To American National Red Cross: for a good table of contents in annual report.

To *Public Health News*, New Jersey Department of Health: for an index for the year.

RADIO

Tell us of your radio dates ahead, with or without the specific topics?

Station WEEI will broadcast for the Massachusetts Society for Mental Hygiene on alternate Mondays at 2:30 p.m., eastern time: Dec. 2, 16, 30, Jan. 13, 27, Feb. 10, 24.

Probably the A. M. A. will continue broadcasting at 11:15 and 8:00 p.m.,

central time; Station WBBM (770 kilocycles—389.4 meters).

From the code of ethics adopted by the National Association of Broadcasters:

This radio station agrees that patent medicines or products of any kind, the use of which without the advice of a physician may prove dangerous to the health or physical condition of a user, shall be permitted time on the air only when competent medical authorities have approved them.

Caring for the Health of 6,000,000 People, by Homer Folks, over WEEF, October 30. Free from Health Department, New York, N. Y. A good showing of what a health officer or health department must do. Can be adapted to other cities.

Passing Things Around (colds are communicable), radio talk broadcast by Onondaga Health Association, 327 Montgomery St., Syracuse, N. Y. A good example of a "good" radio talk. Free for 2 cents.

DATES AHEAD

The April, 1930, Early Diagnosis Campaign will emphasize "the importance of watching and guarding the child." Inaugurated by the tuberculosis associations, this campaign offers an opportunity for many types of health agencies to participate. Address any local or state tuberculosis association, or the National Tuberculosis Association, 370 Seventh Ave., New York, N. Y.

WORDS

We say "physician" to distinguish between the cult doctors and the physicians. Too often with ignorant people our saying "doctor" means any old kind of a doctor, herb-doctor, advertising quack, or what not. The rest of your cracks on words I agree with.

This, from Bernard P. Roloff, director of health education, Chicago Department of Health, sounds reasonable.

BOOKS AND REPORTS

Laboratory Methods of the United States Army—*Manual of Laboratory Methods* (3d ed. rev.), *Medical War Manual No. 6*—Edited by Charles F. Craig, M.D. Philadelphia: Lea and Febiger, 1929. 696 pp. Price, \$3.50.

This excellent manual appears under a new name, and is practically a new book. It covers an enormous amount of ground, and in all shows a high degree of excellence. There are some omissions, as Kinyoun's modification of Ponder's stain for diphtheria. We cannot but consider it unfortunate that the method of the Wassermann test given is so different from that in general use. In the reporting, (++) represents the highest mark given, indicating complete inhibition of hemolysis. This conforms to the recommendations of the second laboratory conference held in Copenhagen in 1928. An antihuman hemolytic system which requires an excessive amount of complement is used, while the measure of amboceptor necessitates cutting pieces of paper of exactly the same size. Incubation is at 37° C. rather than at icebox temperature. The higher temperature is apt to injure complement and gives more opportunity for non-specific reactions, in addition to which the lower has been found to give stronger reactions with syphilitic bloods. While (++) is the highest mark for the Wassermann, 4+ is used for the Kahn method.

The author, page 186, recognizes that the method adopted by him is less sensitive than that in general use in civil laboratories.

When committees both in Europe and in this country are trying to standardize this test, and to approach a certain degree of uniformity, it seems unfortunate

that a much used and official book should add to the existing confusion. There is no mention of the fact that this is not in accordance with widespread practice.

With a few exceptions, nothing but praise can be given to this manual, both as regards its substance and its make-up.

M. P. RAVENEL

The Chemical Aspects of Immunity—By H. Gideon Wells, Ph.D., M.D. (2d ed.) New York: Chemical Catalogue Co., 1929. 286 pp. Price, \$6.00.

This second edition of an American Chemical Society monograph has been enlarged to include the contributions to immunological knowledge of the past 5 years by the incorporation of new material into the various chapters without increasing their number. As with the previous edition, the underlying idea has been to bring together in the most concise manner possible the best of the facts and theories of immunity for the use of both chemists and immunologists.

This edition will undoubtedly be as widely used as the first, which was translated and published in French and German.

ROY W. PRYER

The Road to Health—By C.-E. A. Winslow, Dr.P.H. New York: Macmillan, 1929. 155 pp. Price, \$2.00.

This is a book written by one who is no propagandist, and who is more than a technician, having the ability to present to us the philosophy of the health movement so that we may see the whole field clearly with him. It covers, in three chapters, the story of the conquest of disease, the dominant phases of the present-day program, and the perplexing problems of the new public hygiene, es-

pecially physician-patient-health agency relationships.

The book is made up of a series of three lectures given presumably to a well educated lay audience. The presentation is convincing, the style pleasing, and it cannot fail to interest and delight readers of the same type as the audience to whom the lectures were addressed.

It is to be regretted that the publishers did not make the book more attractive with illustrations. Reproductions of pictures showing the sanitary measures of older days stimulate interest when contrasted with present-day practice. Simple graphs would have made the few comparative statistics used more comprehensible.

Evidences of lack of editing creep in—for instance, "half the states of the Union (including Pennsylvania) . . ." suggests that this state is inhabited by strange creatures who would not be expected to conform to rational practices. Statements such as "perhaps few of us even in this room" encumber the text.

However, these minor faults mean but little, for the philosophy is so sound, the presentation so convincing, the style so delightful that the book will influence profoundly all those who have better than "tabloid" minds.

R. S. PATTERSON

A System of Bacteriology in Relation to Medicine (Vol. III)—By W. Bulloch, P. Fildes, A. T. Glenny, H. Henry, R. T. Hewlett, R. A. O'Brien, S. G. Paine, G. F. Petrie, Muriel Robertson, R. St John-Brooks, W. G. Savage, A. C. Thaysen, H. G. Thornton, and R. L. Vollum. London: His Majesty's Stationery Office, 1929. 413 pp. Price, \$6.00.

The announcement made some months ago that the Medical Research Council of England would sponsor the publication of *A System of Bacteriology in Relation to Medicine* in 9 volumes was

hailed by all bacteriologists, especially those in English speaking countries, with great satisfaction. Since the creation of the Council, it has been responsible for many notable studies. Certainly no one group has contributed more to bacteriology and many phases of medicine than the Council.

While we have many excellent books on bacteriology in its various relations to human and animal medicine, to agriculture, and to various commercial arts, there is now no system at all comparable to what the Council has projected. We understand that it is to be carried out by some 100 British bacteriologists under the general editorship of Dr. Paul Fildes and Professor J. C. G. Ledingham, who are acting on behalf of the Bacteriological Committee, of which they are members; but which contains in addition the names of other well-known men, so that we are assured of an authentic exposition of the science as well as expert presentation.

The first volume published is No. III. It opens with a chapter on The Economic Aspects of Bacteriology, followed by 11 others, which treat of the bacteriology of water, dairy industry, foods, food poisoning, soil, insects and plants. The diseases treated are bubonic plague, gas gangrene, and tetanus. Each chapter is followed by a well selected bibliography. The presentation, as well as the editing, has been exceptionally well done. The educated Englishman knows his language.

It surprises one to find only 11 pages given to the bacteriology of water, and 23 to the dairy industry, though it must be confessed that it is a relief to have known facts presented succinctly, without the long discussions sometimes found, and which generally result only in confusion. The bibliographies before mentioned point the way to fuller discussion if deemed necessary.

A striking feature of the book is the paucity of illustrations. Only Chapter

V on Soil Bacteria is illustrated. While a book can be overloaded with charts and figures, they are of great assistance in the understanding of certain subjects. One wishes particularly for illustrations of insects and of the organisms associated with gas gangrene.

The Table of Contents is full, and must serve as an index until Volume IX is published, which will contain a general index of the series.

We cannot but feel that the Medical Research Council has put all bacteriologists under a further debt of gratitude, and we congratulate the editors as well as the individual authors upon their excellent work.

M. P. RAVENEL

Some Methods for the Prevention of Tuberculosis—By *W. Bolton Tomson, M.D.* New York: *William Wood*, 1929. 148 pp. Price, \$2.50.

Methods for the control of tuberculosis may be grouped into (a) devices for preventing massive infection and (b) attempts to inhibit the development of disease after infection has taken place. Dr. Tomson has collected in one volume several of the tested measures employed in European countries and in the United States.

The Grancher system, practiced mostly in France and Belgium, is based on the observation that children of tuberculous parents are in grave danger of becoming massively infected and later diseased, and advocates the separation of children from their parents until they have acquired a reasonable amount of immunity. The Grancher principle is applied most drastically by the Placement Familial des Tout-Petits, which arranges for the complete separation of the new-born infant from its mother. The child is cared for at a maternity clinic for about 3 years, after which it is boarded out in a peasant family free from tuberculosis. Of 434 children so cared for in 1927, only 1 died of tuberculosis.

In Switzerland, children are not boarded out in families but are placed in preventoria. Norway and Sweden have developed well rounded programs for the prevention of tuberculosis, in which nursing homes for tuberculous children, open air schools, and improvement of housing conditions, play important parts. In England, prominence is given to the view that infection may be prevented from developing into serious disease by raising the bodily resistance and by diminishing the strength or sizes of the infecting doses. Tuberculosis Village Settlements, such as Papworth at Cambridgeshire and Preston Hall at Aylesford, have demonstrated, according to Dr. Tomson, the feasibility of colonizing tuberculous adults and their families.

The description of some of the measures in vogue in the United States leaves much to be desired both in accuracy of presentation and point of emphasis on the methods selected for discussion.

Dr. Tomson strongly advocates the adoption of the Grancher system for his own country, England, but realizes that public sentiment is strongly opposed to the radical separation of children from parents. American health workers will do well to give careful consideration to the technics described, even though they may not seem suitable to our conditions.

H. E. KLEINSCHMIDT

Laws Concerning Birth Control in the United States—*New York: Committee on Federal Legislation for Birth Control*, 1929. 39 pp. Price, \$.25.

According to this pamphlet, presenting a survey of federal and state legislation on birth control, 31 states now have laws permitting physicians to give information on the prevention of conception, while 11 others permit the giving but not the publishing of the information, and 2 states allow it for the cure and prevention of disease. Four states

are said to be doubtful, and 1 prohibits the information. Following a preface by Margaret Sanger, in which birth control is characterized as a beneficent social force, the various state laws are tabulated, and briefly discussed. The pamphlet will be of interest to those who are either for or against this so-called social force.

JAMES A. TONEY

Meat through the Microscope. Applications of Chemistry and the Biological Sciences to Some Problems of the Meat Packing Industry—By C. Robert Moulton, Ph.D. Chicago: University of Chicago Press, 1929. Price, \$5.00.

This book is one of the Institute of Meat Packing Studies, and is the outcome of a series of lectures given by the author in the school year 1923-1924, though it contains much new material, and may be regarded as a new work.

The name is misleading, as it considers the problems of chemistry, bacteriology, and other biological sciences as related to the meat packing industry. As a textbook for those going into this business, it possesses great value. Health officers should also have knowledge of much of the material presented.

The treatment of meat curing and meat spoilage, which occupies more than one-third of the book, will be of value to many readers, though it is too technical for the general public. The chapter on "Pharmaceuticals and Glands" is of particular interest, showing how large a part the stockyards of today play in the provision of these comparatively new products, much used, and much abused, in rational medicine as well as quackery.

The book is well and interestingly written, and a fair division of space is given to the subjects considered. The last chapter, "Health Problems," while it contains useful information, is not complete enough to be of much value. One cannot help wondering why un-

dulant fever, septic sore throat, ergotism, milk sickness, potato poisoning and fish poisoning should be treated in a book devoted practically entirely to packing house problems, and in the same chapter 11 pages are devoted to the cattle grub, which, while it interferes with the proper growing of cattle, seems to be of interest to the author chiefly because it injures the hides.

The book is excellently printed and bound, and very free from mistakes.

M. P. RAVENEL

Behavior of the Young Child—By Ethel B. Waring and Marguerite Wilker. New York: Scribner, 1929. 121 pp. Price, \$1.00.

In the book, *Behavior of the Young Child*, by Ethel B. Waring and Marguerite Wilker, the two important subjects of sleeping and feeding with relation to young children are considered in terms of practical experiences related and interpreted. The behavior of children in relation to both of these subjects is considerably varied and important.

Many mothers who think they have peculiarly unique problems will probably gain a great deal of information and assurance through seeing in new relationships their own problems. It is extremely important for the adult to understand the underlying reason which exists in the mind of the young child and which determines his behavior.

We cannot always be sure that the behavior approved by adults is necessarily best for the young child. Sometimes very serious defects occur in the child's behavior because of the disapproval expressed by adults who do not fully appreciate the fact that each age group has its own behavior code which often meets the approval only of its own age group. Many a child is today not eating or sleeping because of insistence upon his sleeping or eating in a way which meets only adult approval. This

is a point, I think, 'brought out in the examples cited in the book.

Adults whose experience has been very limited in the care of young children should benefit greatly by seeing the variety of responses that can occur in a single situation. The distinction is clearly made between what we really do teach the child and what we wish to teach the child. The book is helpful and instructive. LEROY A. WILKES

Rickets Including Osteomalacia and Tetany—By *Alfred F. Hess, M.D.*
Philadelphia: Lea and Febiger, 1929.
485 pp. Price, \$5.50.

Few subjects have held the interest of the scientist and medical man during the last ten years more closely, and few have brought more surprises in their solution, than rickets. The author was led to his study of the disease incidentally during the investigation of infantile scurvy, but for the past 12 years has given his attention both in the clinic and laboratory to its investigation.

Though rickets was satisfactorily described by Soranus of Ephesus, who lived in the early part of the Christian Era, the author divides our concept of the disease into two periods—1650 to 1918, and the second, which he calls that of the "Newer Rickets," from 1918 to the present. The date 1650 was presumably selected because in that year the work of Glisson which "will always remain one of the glories of English medicine" appeared.

Rickets is regarded as essentially a climatic disorder. Its distribution throughout the world is inversely proportioned to the amount of sunshine. "In general, a map of the incidence of rickets is the practical equivalent of a map of deficiency of sunlight." This justifies the statement that had physicians during the World War known of the specific value of sunlight or of ultra-violet rays, the so-called "war osteomalacia" would not have flourished.

The study of the disease has also brought about other remarkable discoveries, such as the activation of cholesterol, and the further discovery that ergosterol was really the substance concerned. The remarkable effects of the ultra-violet light have also been demonstrated to such an extent that "Rickets has become the established criterion for appraising the biological action of ultra-violet waves in the region of 300 millimicrons."

The author has produced what we consider a complete book in spite of his apologies for some omissions. There are few questions which remain unanswered. From the standpoint of our readers, the prevention of rickets with its resulting deformities will prove the most interesting feature, but this has, of course, depended upon the experimental and practical studies described. A clear understanding of all the factors involved is especially important on account of the commercial exploitation of irradiated foods and irradiation in general.

Osteomalacia and infantile tetany are also capably considered. We cannot but consider this a book of unusual importance, both as regards subject matter and treatment. It will for a long time hold its place as a standard.

There are few illustrations, but there is a well selected bibliography. The printing and make-up are of high quality.
M. P. RAVENEL

Federal Limitations upon Municipal Ordinance Making Power—By *Harvey Walker.* *Columbus: Ohio State University Press, 1929.*
207 pp. Price, \$3.00.

Among the many technical requirements of ordinance making is the essential one that the ordinance must conform to all provisions of the Federal Constitution. The several limitations imposed by our supreme law, and the interpretation and application of them

as revealed in the numerous decisions of the Supreme Court of the United States have been compiled, documented, and studiously set forth in this well printed book. It does not contain much specifically on the subject of public health, though half a dozen pages are devoted to a discussion of local health powers in relation to the Fourteenth Amendment to the Constitution. Lawyers, legislative drafting experts, and others concerned with the legal technic of ordinance making will find this book of value for reference and study.

JAMES A. TOBEY

Water Supply Engineering—By *Harold E. Babbitt and James J. Doland*. New York: McGraw-Hill, 1929. 776 pp. Price, \$6.00.

This up-to-date textbook has been prepared in such a way as to combine both fundamentals and practical procedure. The limitations of space and cost have, of course, prevented exhaustive treatment of each subject, but sufficient is given to fulfil the purpose of the volume. It is believed that the readers will be struck particularly with the logical arrangement of the subject matter.

After a brief introductory chapter and one on finances, there follow two good ones on hydraulics and rainfall and runoff. As these two subjects are important ones to the student, they are given more space than some other subjects. Dams, impounding reservoirs, intakes and aqueducts are given 71 pages, while steam and electrical power, together with pumping machinery, receive 113 pages or a little more than one-seventh of the book. Because of the extensive use of electricity as power, the chapter on the utilization of that power is appropriate.

The next group of chapters covers materials, pipes, and the design and maintenance of distribution systems and reservoirs. This leads into a series of

chapters covering 224 pages on sanitation, and water quality and its purification.

The book has a good table of contents and is well indexed.

ARTHUR P. MILLER

The Doctor in Court—By *Edward Huntington Williams, M.D.* Baltimore: Williams & Wilkins, 1929. 289 pp. Price, \$3.00.

This is not a law book, but a story book. It is full of absorbing anecdotes from the experiences of a doctor who has frequently been in court during the past 40 years. The author belongs to the phratry of alienists, and admits it. As a consequence, most of his narratives are concerned with legal processes affecting the insane, particularly on the west coast. His discussions of the many incidents in his own career as a medical witness, and the appearances of other clever alienists before equally dextrous attorneys, are tinged with numerous ironical comments on the technicality, trickery, and quibbling with which the layman thinks our legal system is infested. Not so much is said about some of the patent imperfections, defects, and inconsistencies of medical science and its representatives, especially when on the witness stand.

Be that as it may, this is a particularly interesting book for any kind of a reader. The pleasure of perusing it, which is considerable, would be enhanced if the publishers had not made the reader cut so many of the pages. The print, paper, and make-up are all excellent, though judging from what is an unusual number of typographical errors for this publishing firm, the author is a better alienist than proofreader. Every physician and every sanitarian who ever has appeared in court, or expects to, and that includes nearly all of them, will find this volume both valuable and interesting. So will the general reader.

JAMES A. TOBEY

Biological Stains—A Handbook on the Nature and Uses of the Dyes Employed in the Biological Laboratory. (2d ed. rev.) *H. J. Com, Chairman. Geneva, N. Y.: Commission on Standardization of Biological Stains, 1929.* 224 pp. Price, \$2.50.

In the preface it is stated:

... in the four years since the first edition of this book was published so much has been added to our knowledge of stains and staining that a large portion of what was then written is now out of date. As a result it has been almost necessary to rewrite the book in revising it. At the same time a good deal of new material has been added.

The improvement, which is significant, lies in the new material. A fairly close comparison with the first edition shows no essential changes from, or deletions of, any part of the contents of that edition despite the claim that a large portion is now out of date. Fortunately the book is better than the preface indicates in this respect, inasmuch as the essential features are still not out of date.

A section on acridine dyes has been added; those xanthene dyes which have come into prominence as indicators are more fully considered; a table of dye solubilities in water and in 95 per cent alcohol is included; and 2 pages of general laboratory information are appended which give the solubilities of certain compounds much used in microscopic work, formulas for fixing solutions and a cleaning solution. The chief addition so far as value is concerned is the including of detailed staining formulas and procedures under the various dyes as well as the general amplification of the list of dyes mentioned in detail. For many this will significantly enhance the value of the book.

To the theoretical portions of the book little if anything has been added, and little significantly altered. Very fortunately, the successful application of staining processes is not dependent on

a knowledge of their mechanism. If this were not the case, there would be little help offered in those chapters which treat on mechanism—either general or of the formation or action of compound dyes. One feels that a more definite knowledge of the types of valence bonds recognized by chemists would have been of aid. Though the confusion of the reaction of a solution with "basicity" or "acidity" of a compound is less evident here than in much biological writing, a trace of it remains. A certain limitedness of physical and chemical outlook is evinced throughout these particular chapters, an instance of which is the naïve statement (p. 161) indicating that the phenomenon of adsorption is the property "possessed by a solid body" rather than one characteristic of any type of interphase, even though the latter definition would aid the argument unless one assumes stained tissue as almost invariably solid.

The book is valuable as a compend of practical information, but the theoretical chapters should be read with an open mind, even if with interest.

The pointing out of these weaknesses does not detract from the general value of the book, and we feel that all of those interested in stains and staining owe a debt of gratitude to the Commission, and especially to its chairman.

A. E. STEARN

A Manual of External Parasites—
By Henry Ellsworth Ewing, United States Bureau of Entomology. Springfield, Ill.: Charles C. Thomas, 1929. 225 pp. Price, \$4.50.

The five major groups of external parasites, the mites, ticks, biting lice, sucking lice and fleas, are treated in a technical yet readable manner. The manual gives a very good background for the study of these different groups. Original keys to the known genera of the world are given in most instances. These together with other essential

taxonomic matter and the consideration of external anatomy, life histories, natural relationship and economy make the book a valuable guide and reference for students of these groups. While it is intended more particularly for biological students, the manual will serve as a valuable reference for the general practitioner and the specialist in skin diseases and external parasites. Those interested in the veterinary sciences will also find it very valuable to them in their work.

The average layman will be particularly interested in the discussions and recommendations on the control and prevention of annoyance from the common chiggers. The chapter on parasitic mites has been handled in a masterful manner. Stockmen and poultrymen will be especially interested in the chapters on ticks and the biting and sucking lice. These three groups have been handled in a very satisfactory manner. The chapter on fleas will interest all who have ever had contact with this most annoying group of parasites.

The systematic arrangement of subject matter, the keys and excellent illustrations, mostly original, combine to make this brief manual a most valuable and acceptable addition to the literature on the external parasites.

L. HASEMAN

The Bureau of Prohibition. Its History, Activities and Organization—By Lawrence F. Schmeckebier. Washington: The Brookings Institution, 1929. 333 pp. Price, \$2.00.

Here is one really dispassionate account of the federal bureau whose activities in enforcing narcotic and liquor laws seem occasionally to cause public agitation, apprehension, and excitement. Mr. Schmeckebier has set forth in an impartial, almost blasé, manner the brief history and the extensive organi-

zation and activities of the Bureau of Prohibition. In this well printed volume, there are also included a number of valuable appendices giving compilations of laws and other useful data. There is a good index.

Physicians concerned with the intricacies of dispensing medical alcohol and narcotics will find this tranquil contribution to a turbulent subject a valuable reference work.

JAMES A. TOBEY

Report of the Second Laboratory Conference on the Serodiagnosis of Syphilis—League of Nations, Health Organisation, Official No. C. II. 726. III. Health, 1929, III, 3. Boston: World Peace Foundation. 186 pp. Price, \$1.00.

Considering the number of methods available for the serodiagnosis of syphilis, it is no small problem to select one for use in the average laboratory. Usually the choice depends on anything but a careful comparison of those in common use. It must be with some disappointment that the laboratory director, desirous of having the best, views the report of the Conference on the Serodiagnosis of Syphilis. The Conference was held for the purpose of making a comparative study of the various methods in use. Thirty-seven workers from 19 countries applied 1 of 16 tests to the serological detection of syphilis in 944 serums. The results, together with the clinical diagnosis on the patients from whom the serums were obtained, are published in detail, but the comparison must be made by the reader himself. The Conference, if it made a comparison, found it impossible to recommend any single test, although it must have had an opinion, for it declared: "the best of these (precipitation tests) may be regarded as equal in value to the best of those which depend on fixation of complement."

Rather than present an opinion on

the matter, the Conference made a series of recommendations which, if they should be considered as the accomplishments of the session, would place it on a par with some disarmament conferences. Fortunately, one is privileged to study for himself the tables presented and draw his own conclusions. Hence, there may be a result other than the following, which are in brief the recommendations of the Conference:

1. Precipitation tests should be done only by trained serologists.
2. At least two different methods should be used.
3. The tests used should be checked by frequent conferring with the clinician.
4. A uniform method of reporting (+, \pm , —) should be used.
5. On reports should be printed certain warnings for aid in interpretation of results.
6. Clinicians should study closely the diagnostic and therapeutic implications of the reports.
7. Further comparisons of this kind should be made in the future.
8. The Danish State Serum Institute should distribute serums for comparative study; itself test serums, and act as an intermediary for the exchange of information.

That these recommendations have worth, although some of them are already actively challenged, is evident, but it would almost seem that as a net contribution of such an ambitious undertaking they are disappointing.

Aside from the recommendations the report submits the entire data accumulated, including, besides results, a summary of the technical details of the methods used, and statements from several workers explaining the apparent failures of certain tests.

The reader will find difficulty in reconciling the data with the recommendations of the conference. If there is any reason for saying "the best of the precipitation tests equal to the best of the complement fixation tests," it is found in data not presented in this report, for here it is so apparent that precipitation

tests were infinitely superior that American champions of complement fixation tests explain the discrepancies by complaining of the antiquated methods in use in Europe. Had Kolmer been present results would have been different, it is claimed. It is indeed unfortunate that the Kolmer methods were not included. The omission was not the fault of the Conference.

This report should certainly be in the hands of every person engaged in the serodiagnosis of syphilis. Aside from its value in tabulating results of a large number of comparative tests, it provides interesting reading for the philosopher.

N. W. LARKUM

Eat and Be Happy—By Josiah Oldfield, M.D. New York: Appleton, 1929. 115 pp. Price, \$1.50.

As if there were not a plethora of books on how to eat, this publishing firm has acquired one by an English writer. Judging from the result there was little, if any, justification for such temerity. Not only is this particular book no better than the average, which is non too good, but it is much worse. The erudition and modernity of the author is well displayed by the archaic statement that if a man "lives over a bad-smelling drain, he will be always suffering from some complaint or other." A chapter on rheumatism is distressingly naïve, while one on vitamins omits more of them than are described.

"Every food faddist," declares the author, "should be put upon a pillar as high as that of Simeon Stylites or hanged on a gallows as high as Haman's." Excellent advice, which if followed would have meant that this book would never have been produced. It is indifferently printed and has no index. Considering its quality and quantity, or lack of both, the price asked for the book seems excessive.

JAMES A. TOBEY

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

White Plains, N. Y.—A birth rate of 23.7 per 1,000 population, with 78 per cent of the births occurring in 2 hospitals of the city, is the record of this city of 31,069 inhabitants for the year 1928. A general death rate of 11.9 and an infant mortality rate of 40 (24 for first month) are noted.

The medical service of the Department of Education supervises the health of school children at a cost of 62 cents per capita. A bedside nursing service with 8 nurses is maintained by the volunteer nursing association at a cost of 77 cents per capita. Hospitalization of indigent cases of contagious diseases, including venereal diseases and tuberculosis, is handled by the department of charities at a cost of \$1.72 per capita. The health department budget amounted to \$1.21 per capita. The health work of the city, scored on the basis of the second edition of the *Appraisal Form for City Health Work*, receives a rating by the health officer of 897, while the score on the third edition amounts to 783, the greatest difference occurring in the results in preschool hygiene work. The report contains excellent tables of vital statistics.

During the year there was conducted a toxin-antitoxin campaign by the health department in coöperation with the Board of Education, the Medical Society, the County Committee on Tuberculosis and Public Health, the Chamber of Commerce, the Nursing Association and the Parent-Teacher Association. Some 43 per cent of the preschool children, 83 per cent of children 5 to 9 years of age and 66 per cent of children 10 to 14 years of age received 3 immunizing doses. There was only 1 death from diphtheria of a child in White Plains during the year.

Attleboro, Mass.—One of the major health projects of the city of Attleboro is the health camp for undernourished boys, established in 1923 with the objective of developing boys mentally and socially as well as physically. In 1928 a group of 40 boys ranging in age from 7 to 14 and averaging 15.2 per cent underweight, was accommodated. The net gain during the 6 weeks of camp was 308 pounds, the maximum gain 12¾ pounds and the average gain 7¾ pounds. Posture work was an important feature of the camp program.

A noticeable decrease in the tuberculosis incidence and mortality is reported. In 1928 there were 74 cases with 24 deaths. Exclusive of non-resident cases the city had 8 cases with 6 deaths. This city of 21,330 people (estimated population) records a death rate of 12.6 per 1,000 inhabitants and an infant mortality rate, exclusive of stillbirths, of 61.5. Organic heart disease (30), pulmonary tuberculosis (23), chronic myocarditis (22) and cancer and cerebral hemorrhage (19 each), lead the list of causes of death for the year.

The health officer offers the following recommendations as a means of improving health conditions in the city: The appointment of a full-time milk and sanitary inspector, Appropriation for a properly supervised dental clinic, Isolation facilities for contagious diseases.

San Joaquin, Calif., District—A review of the operation of the San Joaquin local health district for the years 1923-1928 is highly enlightening. A local health district for administrative health purposes was formed by the county board of supervisors supported by representative citizens in 1923. This district provides for a governing Board

of Trustees who is concerned with the operation of the health department only. On this Board, each incorporated city has a duly appointed representative answering to the governing body which appoints him, namely the city council. The rural area is also represented by an appointee of the Board of Supervisors.

For the year 1927 a death rate of 12.17, an infant mortality rate of 61.7, a typhoid rate of 2.9, a diphtheria rate of 2.9, and a tuberculosis rate of 139.8 are recorded. Each of these rates is a marked reduction over the years preceding the formation of this coördinated district health program. Stockton, a city of over 50,000 people, completed 3 years without a death from diphtheria.

It is conceded that public health service does cost money—so do fire and police departments. While the latter two serve to some extent as life savers, it must be admitted they are more largely concerned with the protection of property. Property can be replaced—human life cannot. San Joaquin citizens believe in health conservation as a matter of economy as well as of humanitarianism.

National Federation of Day Nurseries—This biennial conference report is bound in attractive covers which immediately arouse interest, and cause the reader to turn the page and read the reports which prove to be most interesting.

The relation of diphtheria protection to nurseries, and the organization and functions of the nursery school are discussed at some length.

The nursery and nursery school have come to stay. Already the so-called privileged classes are clamoring for their children to have the daily opportunities, contacts, education and supervision of the nursery school, and now working mothers are glad to work harder that they may give to their little ones the same advantages.

In 1844 the first real "creche," or day nursery, was opened in Paris, supported partly by the city government and partly by private donations. Two years

later the Society of Creches was formed. Within 40 years, 67 "creches" were formed in Paris, 44 in the suburbs and 223 in the departments and colonies.

Since 1907, with the founding of the National Society of Day Nurseries in England, the day nursery there has taken on new life. All its nurseries are licensed and partially supported by government or municipal aid.

In the United States, the nursery began in Troy, N. Y., in 1856, and after 73 years it is still working and has an average attendance of 100 children a day.

Jamaica—The 1928 account of public health work on the island shows progress in the control of disease. "The Colony has learned that public health is purchasable and that a full realization of the benefits to be derived from health conservation can be found only in providing and maintaining well equipped health departments."

During the year the International Division of the Rockefeller Foundation co-operated with the government of Jamaica in rural sanitation and hookworm control, health education, school hygiene and dental clinics, a school for sanitary inspectors, a malaria survey, a tuberculosis survey and dispensary, and parochial health work. During the past 10 years, marked improvement has been made in living conditions as well as in public health, and expenditures of the central and local boards of health have more than doubled.

Seeing Through Life—This is the title of the annual report for 1928 of the National Society for the Prevention of Blindness. This is an unusually attractive report, concisely written, appropriately illustrated, and well printed on good paper, easily read. All but 12 states and one territory supply free prophylactic solution either to midwives or to doctors or to both, while 30 states

carry provision on birth certificates for reporting the use of a prophylactic in the eyes of the new-born. About 4 of every 10 birth infections of the eye that become a menace to vision are not gonorrheal in origin. Another fact of importance is the knowledge that treatment of the syphilitic expectant mother in the first 3 months of pregnancy is a safe assurance of her bearing a healthy child free from syphilis or any of its ravaging effects.

The number of sight saving classes in the United States has grown from 292 in 1927 to 305 in 1928. But it is stated that 4,700 more classes are needed. Factors of importance in sight conservation are cleanliness and care, periodic eye examination, adequate medical attention, and adequate and proper lighting. Prevention of accidents in play, safeguarding of industry, preschool eye testing and good habits of eye care are among the preventive factors emphasized. The experience of 583 industrial plants employing more than 578,000 men and women during 1926 and 1927 indicates that in the 2-year period, 2,757 men and women were saved from serious injury or total blindness in both eyes, and 4,654 were saved from serious injury or total blindness in one eye.

Willesden, England—The 53d annual report for the year 1928 shows an estimated population of 176,589, a birth rate of 15.1, a general death rate of 9.78, and an infant mortality rate of 57. At the municipal clinics, expectant mothers attended medical consultations on 2,376 occasions; nursing mothers, 11,336; and children under 5 years, 27,075; a total of 40,787 attendances. Of 2,666 children born during the year, 33.6 per cent subsequently attended welfare centers. A maternal mortality rate of 3.4 per 1,000 births is noted for residents.

The following groups of school children were medically examined: (1) All

children admitted to school for the first time; (2) All children between 8 and 9 years of age; and (3) All children between 12 and 13 years of age, together with children over 13 years of age who have not been examined on reaching the age of 12. There were 21,211 scholars on the public elementary school rolls, while the number of children medically inspected at routine and special inspections was 16,327.

The school nurses visited the homes of children having defects, 20,104 medical defects and 5,925 dental defects. Of those defects found to require treatment, medical or dental treatment was obtained for 14,391 and domestic treatment was obtained for 4,647. Some 88 per cent of the medical defects were treated, 63.5 per cent receiving medical treatment and 24.6 per cent, domestic treatment.

England and Wales—The annual report of the Chief Medical Officer of the Ministry of Health of England and Wales for the year 1928, like the previous reports from this source, is a highly enlightening and stimulating document.

In a word, preventive medicine means the organization of human nurture—the cultivation and health of maternity, infancy, childhood, adolescence, adult life, old age, the postponement of mortality; and such cultivation means not only the central and local provision of medical and sanitary agencies for the fuller control of morbid processes, but the development of the body and mind of man that they may reach, in each individual, the top of their capacity. Nothing is more certain than the fact that the physical advancement and health of mankind is dependent not upon a "doctor's stunt" here or a "sanitary institution" there, but upon the whole social environment and evolution of the people.

Four basic principles must be fulfilled; it is stated, before sound foundations of a national system of preventive medicine may be laid. There must be ascertainment and accurate registration of the data obtainable. There must be

a standard of health and physiology. It is desirable to formulate an average and a norm, primarily on physiological facts. There must be an ever-growing knowledge of pathology, the nature of disease, its character and incidence, its causes and predisposing conditions, its mode of spread, the social factors which increase or reduce it, and the means of its treatment and prevention. Finally, there must be national organization.

Illinois—During 1928 the 50th anniversary of the establishment of state public health service in Illinois was celebrated. This occasion was commemorated by holding in Springfield a special program participated in by distinguished sanitarians and educators. This anniversary was also the occasion for the

publication of a 2-volume history of health conditions and public health service in the state. A review of these historical documents has previously appeared in these columns of the JOURNAL.

The annual report for the fiscal year ending June 30, 1928, is abundantly illustrated with statistical charts of comparative death rates for the years 1920 and 1927. A general death rate of 11.4 in 1927 compares with a rate of 12.7 in 1920.

Under public health education it is noted that during the year, nearly 900,000 pieces of literature were distributed; 1,800 posters and 752 films were loaned, the attendance at meetings where films were shown being 336,700. A large portion of the report of 507 pages is devoted to vital statistics.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Future Medical Practice and Health—Indications of the trend of medical practice are examined, and the opinion is offered that more organization is inevitable. The author hopes to see this organization accomplished with the preservation of the essential characteristics of independent practice. A stimulating paper.

ARMSTRONG, D. B. What Direction, Please? *New England J. Med.*, 201, 21: 1039 (Nov. 21), 1929.

Raw Milk—The term *contaminated* is suggested as a substitute for *raw*, on the assumption that all raw milk is contaminated milk no matter how carefully produced.

BELL, W. J. Universal Pasteurization Our First Objective. *Pub. Health J. (Canada)*, 20, 11: 531 (Nov.), 1929.

Propaganda about Cancer Control—What the public should be told about cancer and how is discussed at length by this British consultant. Not new, but sound.

BURROWS, A. On Telling the Public about Cancer. *Med. Off.*, 42, 18: 195 (Nov. 2), 1929.

Childhood Tuberculosis Prevention—Case finding by routine skin tests combined with X-rays when indicated are among the preventive measures discussed. Control measures are suggested but a detailed scheme is not worked out.

CASPARIS, H. Tuberculosis in Children. *J. A. M. A.*, 93, 21: 1639 (Nov. 23), 1929.

County Sickness Survey—A morbidity survey in the most sparsely settled county of New York State results in findings comparable, in the main, to those of the preceding rural survey and

provides valuable statistical material.

DEPORTE, J. V. Sickness in Essex County. *New York State J. Med.*, 29, 21: 1311 (Nov. 1), 1929.

Scarlet Fever—A brief summary of the control measures against scarlet fever written by the Dicks.

DICK, G. F., and DICK, G. H. The Control of Scarlet Fever. *Am. J. Dis. Child.*, 38, 5: 905 (Nov.), 1929.

Milk-Borne Scarlet Fever—A detailed account of the epidemiologic study of a milk-borne scarlet fever outbreak which indicated an udder infection in a cow contracted from a boy who milked the cow while suffering from a "sore throat." From drinking the contaminated milk, 202 cases developed.

EAKINS, W. T. A Milk-Borne Outbreak of Scarlet Fever in which Udder Infection with Scarlatinal Streptococci was Indicated. *Pub. Health News (N. J.)*, 14, 12: 259 (Nov.), 1929.

Generalized Nursing—The economy of a generalized nursing service in a rural community is indicated in the study of the problem in Cattaraugus County (N. Y.). A very enlightening paper which should be read by health "authorities" who have violent opinions based upon little experience with this subject.

GAMBLE, L. A., and KING, F. Length of Visits in a Generalized County Nursing Service. *Pub. Health Nurse*, 21, 11: 567 (Nov.), 1929.

Maternal Mortality—"It is most important to make proper and adequate provision for the necessary and suitable training of those who are to practice obstetrics in the future." This is the first and greatest consideration.

HOLMES, R. W., et al. Factors and Causes of Maternal Mortality. *J. A. M. A.*, 93, 19: 1440 (Nov. 9), 1929.

European Infant Mortality—The League of Nations compilation of infant death rates is presented graphically, and recommendations based on the international study are included.

HOLLAND, D. F. The League of Nations' Investigation of Infant Mortality. *Child Health Bull.*, 5, 6: 167 (Nov.), 1929.

Mouth Hygiene—The necessity of teaching the direct relationship between dental disease and health is the burden of this paper. The importance of the first molars is stressed.

HYATT, T. P. Mouth Hygiene Education. *Connecticut Health Bull.*, 43, 11: 395 (Nov.), 1929.

The Cigarette Evil—Medical opinions that, under certain conditions, smoking is detrimental to health are marshalled effectively to refute the recent opinion handed down by a disinterested doctor from North Carolina, implying that tobacco's chief harm lies in a slight local irritation to the throat. The author attempts to make a case for the dire effect of nicotine upon fetal life, a conjecture for, or against, which no real scientific evidence has been presented. One of his correspondents makes a good reply.

KNOPE, S. A. Effects of Cigarette Smoking. *M. J. & Record*, 130, 9: 485 (Nov. 6), 1929.

Sero-Diagnosis of Syphilis—A step-by-step examination of the serological tests of value in the diagnosis of syphilis. The Wassermann (Kolmer modification) is more sensitive and less liable to nonspecific reactions than the Kahn or other serum tests. An answer to many of the claims made for the latter tests.

KOLMER, J. A. Truths about the Serum

Diagnosis of Syphilis. *J. A. M. A.*, 93, 19: 1429 (Nov. 9), 1929.

Nutritive Value of Fat—In addition to providing an excellent source of body heat, fats regulate the rate of digestion, enable the bulk of diet to be restricted, and supply fat soluble vitamins.

MACLENNON, K., and WILLIAMS, P. N. The Nutritive Value of Fatty Foods. *J. State Med.*, 37, 11: 654 (Nov.), 1929.

Malnutrition and Tuberculosis—A British investigation reveals many malnourished children in tuberculous households. The author believes that much can be done to prevent the spread of the disease by clinic care for malnourished contacts.

MORGAN, F. C. Malnutrition in Children in Relation to Tuberculosis. *Med. Off.*, 42, 20: 217 (Nov. 16), 1929.

British Vaccination Procedure—The British ministry's recommendations of the "one insertion" vaccination method, the primary vaccination of infants, etc., are reported in this discussion of post-vaccinal encephalitis. This paper will furnish new material for the indefatigable news-hunters of the anti-vaccinist societies who wade through even this inoffensive column in their search for statements to distort. Health workers will find useful information in the paper.

McKINNON, N. E., and DEFRIES, R. D. Recent Recommendations in Vaccination. *Pub. Health J. (Canada)*, 20, 11: 552 (Nov.), 1929.

Nursing in Social Hygiene—What one nursing association plans to do (some day) as its share toward the solution of the social hygiene problem. The day may come when all health agencies will ask themselves whether they are doing their part in this neglected field of public health.

PAGAUD, M. V. Nursing Problems in a So-

cial Hygiene Program. *Pub. Health Nurse*, 21, 11: 571 (Nov.), 1929.

Another "Cold" Germ—To the long list of bacteria and filtrable viruses causing common colds, an intrepid bacteriologist adds another. This one is an aerobic micrococcus which, grown in pure culture, will produce the disease in subjects from whom the organism is again recovered.

PFEIFFER, J. A. F. An Undescribed Organism Isolated from Acute Rhinitis. *M. J. & Record*, 130, 9: 497 (Nov. 6), 1929.

More Maternal Mortality Causes

—Lack of prenatal care; failure in aseptic practice; interference with normal labor; unnecessary cesarean sections; undue value on child's life; cross infection; hurried labor. These are the avoidable causes of our high puerperal mortality and morbidity, say these authors.

POLAK, J. O., and CLARK, C. Puerperal Morbidity and Mortality. *J. A. M. A.*, 93, 19: 1436 (Nov. 9), 1929.

Los Angeles Health Administration

—The story of the unique development of disease prevention and health promotion in Los Angeles County (Calif.). It would be unfair to spoil the health officer's excellent account by attempting to characterize it in this brief space. It will be read.

POMEROY, J. L. Health Center Development in Los Angeles County. *J. A. M. A.*, 93, 20: 1547 (Nov. 17), 1929.

Diphtheria Immunity and Tonsillectomy

—Of 100 Schick positive children whose tonsils were removed, 82 were Schick negative 6 months after the tonsillectomy was performed. The authors offer several possible explanations

of the phenomena observed, but wisely refrain from drawing conclusions. Many health authorities ought to be in a position to gather evidence to support or contradict the reported observations.

SCHICK, B., and TOPPER, A. Effect of Tonsillectomy and of Adenoidectomy on Diphtheria Immunity. *Am. J. Dis. Child.*, 38, 5: 929 (Nov.), 1929.

Negro Infant Mortality

—Urban infant death rates are invariably higher than rural. The latter are about the same as for whites in similar areas. The causes of infant deaths are enumerated and compared with white infant mortality.

STOUTCHON, A. L. A Study of Negro Infant Mortality. *Pub. Health Rep.*, 44, 45: 2705 (Nov. 8), 1929.

Health Administration Abroad

—How the Hamburg (Germany) health work is carried on is recounted in this intensely interesting study. The general sickness rate is low; smallpox is unknown; common communicable diseases are uncommon; general debilitating conditions are rare. Of course, we in super-progressive America have nothing to learn from the backward, old countries. But read it, anyway.

TOWNSEND, J. G. Public Health Organization and Administration in Hamburg, Germany. *Pub. Health Rep.*, 44, 47: 2847 (Nov. 22), 1929.

Tuberculosis Vaccination

—Chalk up another victory for Calmette's BCG. The author's experience leads him to urge the vaccination of all infants born to parents with open pulmonary tuberculosis.

WEBB, G. B. Immunization against Tuberculosis by *Bacillus Calmette-Guérin* (BCG). *J. A. M. A.*, 93, 19: 1459 (Nov. 9), 1929.

NEWS FROM THE FIELD

STANDARD SAFETY CODE

A NATIONAL standard safety code for building exits aimed to cut down the annual loss of 15,000 lives by fire in the United States has just been approved by the American Standards Association and made available for adoption by state and municipal authorities and for use by architects, engineers and builders. The code was prepared by a technical committee of 30 representatives of safety and insurance organizations, federal government departments, state departments of labor, local fire departments, architects, engineers and others. It represents 16 years of study by this committee and its predecessors.

MAX MASON NEW ROCKEFELLER PRESIDENT

DR. Max Mason assumes the duties of President of the Rockefeller Foundation on January 1, 1930. He succeeds Dr. George E. Vincent, who has been President since May 15, 1917. Dr. Vincent resigned from this position as he has reached the age specified for retirement.

Dr. Mason was formerly connected with the University of Chicago, Massachusetts Institute of Technology, Yale University and the University of Wisconsin. He was president of the University of Chicago from 1925 to 1928.

MEXICAN BABY STAMPS

THE Republic of Mexico has issued recently many new stamps among which are the "Baby Stamps," whose object it is to contribute to the fund for the reduction of infant mortality. This fund is sponsored by the Association for the Protection of Infants.

The stamp is light blue in color, and has a picture of a woman with a baby in her arms. The caption under the picture is "Help the Infants."

HEALTH TEST FOR COOKS DECREED BY LAW IN CUBA

STRINGENT new health laws for domestic servants, cooks, nurses and all employees who handle food are to be enforced in Cuba.

The Department of Health is opening a clinic in Havana, where inoculation against typhoid and examination for tuberculosis, diseases of the skin, and blood and intestinal parasites will be carried out.

Inoculation for domestic servants will be compulsory. They will be given a certificate of good health, to be shown when seeking employment.

CLINIC FOR MENTAL AND NERVOUS DISEASES OF CHILDREN

A FREE municipal clinic for children affected with nervous and mental diseases was opened recently in Turin, Italy. This city also maintains a school for mental defectives, the pupils of which are sent for the summer to a mountain camp or to the seashore.

WARSAW HAS NEW HOSPITAL

ON November 15, 1929, the Rockefeller Foundation opened a training school for nurses in Warsaw. This will be conducted by the Polish Red Cross.

NEGRO NURSES

THE Lincoln School for Nurses of Lincoln Hospital, New York, is the largest institution in the country for the training of Negro nurses.

MEASURES FOR INCREASE OF POPULATION

AN Italian law of June 6, 1929, on measures for the increase of population contains the following item:

In the appointment of clerical or manual workers in the Government service, whether national, provincial, or municipal, no preference shall be given to unmarried persons, and, other things being equal, married persons with children shall be preferred to those without children and married persons without children to unmarried persons.

In the assignment of apartments in houses built with Government aid, other things being equal, married persons with children are to be given preference over those without children, and married persons without children over unmarried persons.—*Rassegna della Previdenza Sociale*, Rome, July, 1929, p. 107.

MENTAL HYGIENE MEETING AT NORWICH, CONN.

HAVEN EMERSON, M.D., of Columbia University spoke on November 14, in Norwich, Conn., on "The Place of Mental Hygiene in the Public Health Nursing Program." This meeting was sponsored and arranged by the Mental Hygiene Division of the United Workers of Norwich.

MEETING OF INTERNATIONAL ASSOCIATION OF DAIRY AND MILK INSPECTORS

THE International Association of Dairy and Milk Inspectors held its eighteenth annual meeting at Memphis, Tenn., October 7-9, 1929. Resolutions were adopted relating to the death of Ivan C. Weld of Washington, D. C., who died a few weeks prior to the meeting, and three brief but eloquent memorial addresses were given. Mr. Weld was largely responsible for organization of the Association and had held the office of secretary-treasurer for 18 years. He was a member of a Com-

mission that went to Germany to advise the government as to methods of improving the dairy industry, and at the time of his death was president of the Washington Chamber of Commerce.

The following officers were elected for the ensuing year: President, Ralph E. Irwin, State Department of Health, Harrisburg, Pa.; First Vice-President, Dr. A. R. B. Richmond, Department of Health, Toronto, Ont.; Second Vice-President, William B. Palmer, Director of the Milk Control District of "the Oranges," Orange, N. J.; Third Vice-President, Dr. Horatio N. Parker, Department of Health, Jacksonville, Fla.; Secretary-Treasurer, Dr. Paul B. Brooks, State Department of Health, Albany, N. Y.

VIRGINIA PUBLIC HEALTH ASSOCIATION

THE Virginia Public Health Association held a meeting in Charlottesville, Va., on October 21. There were 30 delegates present.

COUNTY HEALTH DEPARTMENTS FOR MICHIGAN

WITH some aid from the Rockefeller Foundation the Michigan State Department of Health is helping 10 counties to organize their own health departments. A training station at Lansing is being established to provide nurses with the training and field practice in public health work necessary to qualify them for the positions created by these new health units.

The course covers three months' training and can be given to 5 nurses at a time. Other counties are being urged to organize their health work.

DENMARK'S DELICATE CHILDREN

MORE than 1,000 delicate children were sent during a recent year by the Kingdom of Denmark to the vacation colonies which have been established for such children.

HOLYOKE, MASS.

MURRAY P. Horwood, Associate Professor of Bacteriology and Public Health at the Massachusetts Institute of Technology, has just completed a *Health Survey of Holyoke, Mass. With Relation to Tuberculosis*. The report includes a comprehensive study of the vital statistics for tuberculosis, the available facilities for diagnosing tuberculosis, the treatment of tuberculosis in hospitals and sanatoriums, the activities of the Holyoke Tuberculosis Association and other voluntary health agencies, and the organization and activities of the Holyoke Department of Health.

MOTION PICTURES FOR LEPERS

MOTION picture producers cooperating with the Leonard Wood Memorial have recently donated nearly a million feet of film for the use of leper colonies in the Philippines.

PERSONALS

PROFESSOR OWEN W. RICHARDSON of Kings College, London, was given the Nobel Prize in physics. He is a Fellow of the Royal Society of Sweden.

DR. ANNA E. RUDE, director of the Bureau of Maternal and Child Hygiene of the Los Angeles County Health Department, Calif., has been appointed to President Hoover's White House Conference on Child Health and Protection.

DR. FLORENCE R. SABIN of the Rockefeller Institute for Medical Research received the Pictorial Review medal for the woman who has made the most distinctive contribution to American life in the fields of art, science or letters.

DR. LUCIUS S. NICHOLS is the new Health Officer of Geneva County, Ala.

MRS. MARIE DOUGHTY GORGAS, widow of Major General William C. Gorgas,

died suddenly in Washington on November 8.

DR. ALTON S. POPE has resigned as epidemiologist and chief of the bureau of communicable diseases of the Chicago Health Department, and has accepted a position with the Massachusetts State Health Department.

DR. FRANK J. TRACY is the new chief of the clinic for venereal diseases of the St. Louis City Health Department.

DR. RUSSELL H. KANABLE has been appointed superintendent and medical director of the Wyoming State Tuberculosis Sanatorium, Basin, Wyo.

DR. LYMAN W. CHILDS was recently elected president of the American Association of School Physicians.

C. RUFUS ROREM of the School of Business Administration of the University of Chicago has joined the staff of the Committee on the Cost of Medical Care.

I. S. FALK, formerly Professor of Bacteriology at the University of Chicago, has been appointed Associate Director of Study of the Committee on the Cost of Medical Care.

ROBERT P. FISCHER, formerly Secretary of the New Jersey State Board of Pharmacy, is on the staff of the Committee on the Cost of Medical Care on a part-time basis beginning January 1.

CONFERENCES

Jan. 17-18, American Social Hygiene Association, New York, N. Y.

Jan. 27-30, 12th Texas Water Works Short School, Abilene, Tex.

Jan. 27-31, Heating and Ventilating Exposition, Philadelphia, Pa.

FOREIGN

May 19-21, 1930, Second International Malaria Congress, Algiers, Algeria.

July 21-28, Royal Sanitary Institute, 41st Congress and Health Exhibition, Margate, England.

SPENCER

PRECISION

ROTARY

MICROTOME

No. 820

Has Become Worldwide in Distribution, *Because:*

It is built with an incline-plane feed, an advantage possessed by no other rotary microtome. It completely overcomes the inaccuracies usually encountered in rotary microtomes, due to the up-and-down movement of the object. In this microtome the feed and up-and-down movement are entirely independent. Its advantageous features manifest themselves in its perfection of accuracy.

IT IS MADE FOR BETTER SECTION CUTTING

Complete outfit No. 820 with one knife, handle and back for sharpening and with three object-discs \$240.00
New Catalog T-8 Sent on Request.

The Influenza Epidemic of 1928-1929 with Comparative Data for 1918-1919*

SELWYN D. COLLINS, PH. D.

Associate Statistician, U. S. Public Health Service, Washington, D. C.

THE influenza epidemic of the winter of 1928-1929 was by no means the first outbreak since 1918. To get some idea of what has been happening to the influenza-pneumonia death rate during the past decade, weekly data for a group of about 95 cities† have been studied. These cities with an aggregate population of over 30,000,000 are distributed throughout the United States. In order to get a workable population group in such sections as the Mountain States, some cities as small as 12,000 are included. The aggregate population of the 68 cities that had a population of 100,000 or more in 1920 is about the same as the aggregate population of these 95 cities, but the latter group is considerably more representative of the different sections of the country.

In the upper half of Figure I the weekly death rates from influenza and pneumonia combined have been plotted. The dotted line represents the weekly median or expected rate.‡ In the lower half the excess over the median rates have been plotted as an approximation of the extent of the influenza-pneumonia deaths due to the epidemics.

It will be seen that since January 1, 1920, there have occurred six

* Summary of a paper presented before the Epidemiology Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

† Death rates from influenza and from pneumonia for this group of cities have been published weekly in the *Public Health Reports* since January 1, 1925. Published and unpublished reports of deaths in these cities enabled us to carry the record for a large proportion of the cities back to January 1, 1920. Although some of the cities are not included in the earlier years, the group is for the most part identical for the different years.

‡ It may be seen from Figure I that if the epidemic peaks are left out of consideration there is little if any trend either up or down in the actual influenza-pneumonia death rates. The median influenza-pneumonia weekly death rate was, therefore, taken as the "normal," the medians being based on the 7-year period 1921-1927 inclusive. As there was some chance variation in this median rate, the 52 medians, representing the 52 weeks of the calendar year, were smoothed by a 5-period moving average.

FIGURE I.—Weekly total and excess influenza-pneumonia mortality in a group of about 95 cities in the United States, 1920-1929. Dates on graph are middle (Wednesday) of the peak weeks. (Excess over median rates for corresponding weeks for the period 1921-1927. The 52 medians representing "normal" or "expected" rates for the different weeks of the year were smoothed by a 5-period moving average before the excesses were computed.)

more or less definite epidemics. The epidemic of 1928-1929 was the most important since that of 1920. The peaks of these six epidemics occur all the way from the early part of January to the early part of May, and the peak of the pandemic of 1918-1919 occurred much earlier in the fall than was the case in 1928-1929.

The severity of each of the epidemics may be judged to a considerable extent by the weekly excess rates (as given in Figure I), but a more accurate measure would be the total excess rate during the whole period of the epidemic. Table I shows this total excess rate for each of the six epidemics that have occurred since January 1, 1920. Unlike the weekly rates, those in Table I are not on an annual basis.

It will be noted that as measured in total mortality from influenza and pneumonia, the epidemic of 1928-1929 was almost half of that of 1920. If the excess rates as found in these 95 cities are at all representative of the country as a whole, something like 50,000 influenza-pneumonia deaths in the United States occurred during the epidemic of the winter of 1928-1929 in excess of the normal expected number from those causes. The figure for 1920, in agreement with previous estimates, is about 100,000 excess influenza-pneumonia deaths. Dur-

ing the 1918-1919 pandemic, it has been estimated that about 500,000 influenza-pneumonia deaths occurred in this country in excess of the normal expected number, so that the recent epidemic of 1928-1929 caused only about one-tenth as many deaths as the great pandemic. It will be recalled that during the winter of 1918-1919 the influenza-pneumonia death rate remained high for a long period after the peak of the epidemic; in fact, during a period of eight or nine months the death rate was very much above normal.

Table I also shows for each of the geographical sections the total excess rates* during each of the epidemics since 1920. In the 1928-

TABLE I

TOTAL EXCESS * INFLUENZA-PNEUMONIA DEATH RATE PER 100,000 DURING THE WHOLE OF EACH EPIDEMIC IN CITIES OF THE DIFFERENT GEOGRAPHIC SECTIONS OF THE UNITED STATES, 1920-1929

* Excess over the median rates for corresponding weeks for the period 1921-1927. The series of 52 medians representing "normal" or "expected" rates for the different weeks of the year were smoothed by a 5-period moving average before the excesses were computed. It should be noted that the rates in this table, unlike the rates shown in Figure I, are not on an annual basis.

Because the rates in non-epidemic weeks of 1922 are nearly all lower than the median rate 1921-1927, a correction was made for that epidemic by measuring the excess not over the zero base line representing the median rate (Figure I) but over a line parallel to the base line but 25 points (in the rate per 100,000) below it. The amount of this correction varied in the different geographic areas.

1929 epidemic the excess rates in six of the nine sections were practically the same, varying only from 42 to 48 per 100,000. In three sections, the East South Central, West South Central and Mountain, the rates were considerably higher than in the other six sections, the East South Central cities having a particularly high rate.

It will be recalled that, so far as the country as a whole was concerned, the 1922 epidemic was rather small, the epidemics of 1923 and

* Median or expected rates and excesses above those rates were computed for each section in the manner already outlined in connection with the cities considered as a whole.

1926 both being somewhat larger. It will be noted that on the Pacific Coast the 1922 epidemic was rather large, the total excess rate being about four-fifths of the corresponding rate in the 1928-1929 epidemic. The epidemics of 1923 and 1926 were very small in the Pacific coast cities. In the East South Central section the total excess death rate in the 1928-1929 epidemic was nearly as large as that of the 1920 epidemic.

Each of the six epidemics that have been noted as occurring since January 1, 1920, appeared to some extent in nearly all of the nine sections. However, a few sections showed a considerable excess during years that, so far as the country as a whole was concerned, were considered relatively free from influenza. For example, in 1925 the West South Central section showed excess death rates as great as occurred in many sections during the years 1922, 1923 and 1926.

WINTER OF 1928 AND 1929

FIGURE II—Weekly excess influenza-pneumonia mortality in a group of cities in each geographic section of the United States during the epidemic of the winter of 1928-1929. Sections arranged in order of dates of peak mortality as shown in Figure III. (Excess over median rates in the same geographic section for corresponding weeks for the period 1921-1927.)

In Figure II the weekly excess rates for each geographic section are plotted for the short period in the winter of 1928-1929, during which influenza was epidemic. The broken vertical line represents the peak date of the epidemic when the total 95 cities are considered as a group, the excess rates for the whole group being plotted in the lower right hand section of the figure. The peak of the excess mortality occurred on the Pacific Coast early in December. The different sections following the Pacific Coast are arranged in the order of the occurrence of the peaks. Reading the sections down the graph it may be seen that the epidemic followed a very regular course from west to east, ending in New England with a peak about seven weeks later than that on the Pacific Coast.

In contrast to the 1928-1929 epidemic, the 1920 epidemic spread over the country in a very much shorter time. This epidemic apparently started in the East North Central States, around Chicago, from which it traveled east, west and south, ending in the East South Central States with a peak date only about two or three weeks after that in the first section. Figure III shows on a map the starting place and spread of the epidemics of 1920 and of 1928-1929.

FIGURE III—Time of occurrence of two influenza epidemics in cities of different geographic sections of the United States. Darkest sections were first, and lightest sections were last to be affected. (Dates represent estimated peak days for the section, the estimate being made by interpolation within the peak week when account is taken of the rates for the two adjacent weeks.)

The 1926 epidemic, like the recent one of 1928-1929, apparently started on the Pacific Coast. The 1923 epidemic started in the East South Central section and spread rather slowly to other sections of the country. The spread of the epidemics of 1922 and of the spring of 1928 was rather indefinite but the former appears to have started in the East, probably in the Middle Atlantic section, and the latter in the West, probably in the Mountain section. There is, then, no one section where epidemics usually start; in the six epidemics the start has occurred in five different sections.

INFLUENZA MORBIDITY* AS INDICATED BY SPECIAL SURVEYS,
1928-1929 AND 1918-1919

Immediately after the 1928-1929 epidemic the U. S. Public Health Service made surveys in 10 cities in the United States similar to surveys made in about an equal number of cities in 1918-1919. In cooperation with state health departments, some small towns and rural communities were surveyed in Missouri, New York, and Massachusetts. The selected localities of the two epidemics were not identical, but the incidence rates probably give a fairly accurate idea of the number of cases in the two epidemics.

House to house canvasses were made of selected districts with a total population of 10,000 to 15,000 persons in each of the cities to be surveyed.† The two surveys were made along generally comparable lines, but there were some differences in the methods used. In the 1918-1919 survey, the enumerators were instructed to class as influenza such reported "colds" as lasted three days and kept the patient in bed one whole day, unless the case had been otherwise diagnosed by a physician. Other colds were to be recorded as "doubtful," but the number of such doubtful cases reported was so small that it appears that only the more severe colds were remembered by the informants. Attention in 1918 must have been fixed on such cases as were reported as influenza, because of the unusual importance of the disease during the great pandemic. Moreover, the term "doubtful" would suggest to the enumerator, in spite of the instructions to the contrary, that only such colds should be included as might have been influenza.

In the 1928-1929 survey, the enumerators were instructed to inquire about and to record "colds" as such, in addition to influenza, grippe and pneumonia. While the record of "colds" must be incomplete because minor cases were forgotten, it seems reasonable to believe that it contains a larger proportion of the colds that actually occurred than was true of the "doubtful" category of the 1918-1919 surveys. We have accordingly classified the colds reported in the 1928-1929 survey into those causing one or more days in bed and those in which the patient was not confined to bed. For purposes of comparison with the 1918 surveys these colds in bed have generally been included with influenza, pneumonia and grippe as more nearly approximating the influenza, pneumonia and doubtful category of the 1918 data.

Of the cases definitely classified as influenza or grippe, the 1928-

* The data in this section are preliminary and subject to minor changes in later reports.

† For a more detailed statement of the methods, see Veldee, M. V., Morbidity in the Influenza Epidemic of 1928-1929—Preliminary Report on Surveys in Various Cities, *Pub. Health Rep.*, 44, 19 (May 10), 1929. (Reprint 1282.)

1929 rate of 145 per 1,000 persons canvassed is somewhat more than one-half of the rate of 242 per 1,000 in the 1918-1919 epidemic. In the 1918-1919 epidemic the incidence of pneumonia was 16.4 per 1,000, or more than three times the rate of 4.7 cases per 1,000 in 1928-1929. The incidence rate for the group of cases classified as "doubtful," 21.5 per 1,000, in the 1918-1919 surveys was only about half the rate of 39.6 per 1,000 for colds with one or more days in bed in the 1928-1929 epidemic. In addition, there was reported in 1928-1929 a large number of colds (76.6 per 1,000) that involved no days in bed. Considering all the respiratory conditions together, the rate in 1928-1929 was not far different from what it was in 1918-1919, but, as already noted, the 1928-1929 data appear to include a considerably larger proportion of the cases of common colds, such as occur during every winter, than is true of the 1918-1919 data.

Table II shows the case rate for each of the localities surveyed in 1928-1929 and in 1918-1919. Although the localities were not the same in the two surveys (only three surveyed in 1918-1919 were surveyed in 1928-1929), the general picture is perhaps comparable. In this table colds involving one or more days in bed have been included with influenza, grippe and pneumonia because, as already stated, that combination appears to be more nearly comparable to the 1918 data which include influenza, grippe, pneumonia and "doubtful." Another disturbing element is the fact that the period for which respiratory

* 1928-1929 cases include influenza, grippe, pneumonia and colds with one or more days in bed; 1918-1919 cases include influenza, grippe, pneumonia and "doubtful."

FIGURE IV—Case fatality of influenza and grippe in each of a group of localities surveyed in 1928-1929 and in each of a group of localities surveyed in 1918-1919. (Cases in 1928-1929 include influenza, grippe, pneumonia and colds with one or more days in bed; 1918-1919 cases include influenza, grippe, pneumonia and "doubtful.")

attacks were recorded varied in the different localities. In spite of these possibilities of error, it is believed that the data in Table II give a fair picture of the extent and variation of the influenza morbidity rates in a few fairly representative localities in the two epidemics.

The case fatality is hard to determine because it is difficult to estimate how many cases of influenza occurred. Considering all surveyed localities together, the case fatality in the 1928-1929 epidemic was 0.70 per cent if the deaths are related to only the cases definitely reported as influenza, grippe or pneumonia. If the colds that involved one or more days in bed be added to these cases as possible influenza, then the fatality becomes 0.56 per cent. If all colds as well as influenza and grippe be considered as a unit, the fatality is 0.40 per cent. Considering these three statements, it may be said that the case fatality in 1928-1929 was somewhere between one-fourth and one-half of that shown by the surveys of 1918-1919 (1.6 per cent).

Figure IV shows the case fatality for each of the surveyed localities in 1928-1929 and for each of those surveyed in 1918-1919. It may be seen that only one locality, Pittsburgh, reached as high a fatality in 1928-1929 as the average for all surveyed localities in 1918-1919.

As regards the proportion of cases complicated by pneumonia, the percentage also varies according to what type of respiratory attacks are considered as influenza or at least doubtful influenza. In the 1918-1919 epidemic about 6 per cent of the cases were complicated by pneumonia, against from 2 to 3 per cent in that of 1928-1929.

In the 1918-1919 epidemic, the deaths constituted 25 per cent of the cases of pneumonia and in 1928-1929, 21 per cent. It appears, therefore, that the great difference in the fatality of influenza and grippe is due to the difference in the percentage of cases complicated by pneumonia.

TABLE III

PERCENTAGE OF INFLUENZA AND GRIPPE * CASES THAT WERE COMPLICATED BY PNEUMONIA IN EACH OF A GROUP OF LOCALITIES SURVEYED IN 1928-1929 AND IN EACH OF A GROUP OF LOCALITIES SURVEYED IN 1918-1919

* 1928-1929 cases include influenza, grippe, pneumonia and colds with one or more days in bed; 1918-1919 cases include influenza, grippe, pneumonia and "doubtful."

Table III shows the percentage of cases that were complicated by pneumonia. In 1918-1919 nearly 10 per cent of the cases reported in Des Moines were complicated by pneumonia and the average for all of the surveyed localities was nearly 6 per cent. In 1928-1929 the highest percentage of cases complicated by pneumonia was 4.5 for Pittsburgh—a figure considerably below the average of the surveyed localities in 1918-1919.

Figure V shows the age incidence of influenza and grippe in all localities surveyed in 1918-1919 and in 1928-1929. The very high incidence under 30 years of age and the rather rapid decline in the incidence as age increased, which were characteristic of the 1918-1919 epidemic, are not found in the 1928-1929 data. There is, however, one point of similarity—a rather high incidence under 10 years

FIGURE V—Age incidence of influenza and gripe in a group of localities surveyed in 1928-1929 and in a group of localities surveyed in 1918-1919. (Cases in 1928-1929 include influenza, gripe, pneumonia and colds with one or more days in bed; 1918-1919 cases include influenza, gripe, pneumonia and "doubtful.")

of age followed by a considerable drop to a minimum from 15 to 25 years with a rise and a second peak around 30 to 40 years of age. This type of curve seems to run quite consistently through all the localities in 1928-1929. Although not reproduced here, that in general was the description of the age curve of influenza that occurred in Baltimore, Md., during the epidemic of 1920 and in Hagerstown, Md., during the epidemics of 1922 and 1923.¹ It might be stated that the age curves of influenza and of gripe in the 1928-1929 data are very similar, both showing peaks at 5 to 9 and again at 30 to 40 years of age. The age curves for all colds and for colds with one or more days in bed, however, are quite different from the curve for influenza and gripe.

SUMMARY

Influenza-pneumonia mortality data for 95 cities representing all sections of the United States indicate that since January 1, 1920, six

definite epidemics have occurred. If the excess rates in these cities are at all representative of the country as a whole, about 50,000 influenza-pneumonia deaths occurred in the United States during the epidemic of the winter of 1928-1929 in excess of the normal number from those cases. During the six epidemics between 1920 and 1929, something like 250,000 excess influenza-pneumonia deaths occurred in this country—equal to about half of the 500,000 excess influenza-pneumonia deaths in the United States during the pandemic of 1918-1919.

The case incidence of influenza and grippe in the 1928-1929 epidemic as determined by the special surveys, seemed to be more than half of that of 1918-1919. The percentage of cases complicated by pneumonia and the case fatality, however, were much less in the recent epidemic, being in 1928-1929 somewhere between one-fourth and one-half of the corresponding figures for 1918-1919.

1. Sydenstricker, Edgar. The Incidence of Various Diseases According to Age, Hagerstown Morbidity Studies No. VIII, Reprint 1227, *Pub. Health Rep.*, 43, 19 (May 11), 1928.

EXPLANATION: In this paper the terms "influenza" and "influenza-pneumonia" designate the classifications in the recorded mortality that were used and are not intended to suggest that the various respiratory epidemics were necessarily etiologically the same.

NOTE: In the preparation of this paper I have had the advice and assistance of W. H. Frost, M.D., Consultant, and Statistician Edgar Sydenstricker, who, with the author, constitute a board for the study of respiratory diseases appointed by the Surgeon General of the U. S. Public Health Service. Some of the charts here presented will be included in a more detailed article including tabular material which will be published by the Service.

"Bargain" Eyeglasses Ruin the Eyes

THE National Society, for the Prevention of Blindness and the National Better Business Bureau have recently called attention to the fact that certain mail order houses are selling spectacles by mail and that thousands of persons are endangering their eyesight by the use of such glasses which strain instead of aid the vision.

This warning is fully justified, but the organizations in question might well have called attention at the same time to the equally bad practice by department and five and ten cent stores of selling eyeglasses which are fitted (?) by inexperienced salespersons. This practice is a violation of the Education Law in New York State, the legality of which was recently upheld by the Supreme Court of the United States.—*Health News*, Nov. 25, 1929.

What We Know of Influenza and How We May Add to Our Knowledge*

EDWIN O. JORDAN, PH. D., F. A. P. H. A.

University of Chicago, Chicago, Ill.

ON previous occasions I have taken so much time and space in setting forth the scanty nature of our knowledge of influenza that any further detailed discussion of our ignorance seems unnecessary. A few topics, however, appear worthy of brief consideration.

1. The rapidity with which epidemic influenza travels and the large number of persons attacked within a short period gave rise to early conjecture that the disease was borne by the wind or, at least, that it was dependent on general atmospheric or even cosmic conditions which affected nearly simultaneously large masses of people. One writer asserted that "the depraved Constitutions of the Atmosphere are the Causes of almost all epidemic Distempers" (Huxham). Another called influenza "a blast from the stars." These beliefs have died hard and there are still today some observers who maintain that the occurrence of widespread and mysterious fluctuations in susceptibility furnish an adequate explanation for the rise of pandemics. Modern students of influenza are, however, a unit in regarding influenza as a typical infectious disease due to a living, if yet unknown, microorganism. Whatever the origin of pandemics, whatever the possible predisposing effect of obscure cosmic factors, there need be no hesitation in accepting the fact that influenza is a germ disease spread largely, if not wholly, by human agency.

2. The mode of transmission of influenza is necessarily inferential. There is no evidence that water or milk ever serves as a vehicle of infection or that the virus resists drying for considerable periods and is transmitted in dust. The various diseases of domestic animals denominated influenza seem to have no relation to the human infection. The hypothesis of an insect vector appears quite fantastic. The facts that are known about the manner of spread of influenza epidemics accord best with the hypothesis that the disease passes directly from one human being to another, probably by drop-

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

let infection. While no precise information exists as to the relative importance of active cases, convalescent cases, or healthy carriers, in spreading infection, there is reason to believe that persons suffering from the disease in its early stages are particularly likely to convey the infection to others.

3. Since the pandemic of 1918-1919 the laboratory study of the infection seems to have languished, and few bacteriological studies of importance have appeared. This would seem to be due not to any lack of material—for several extensive epidemics have occurred—but to the almost overwhelming technical difficulties involved. The remarkable quality that the influenza virus has of facilitating invasion of the body by many kinds of other microbes, the apparent insusceptibility of the ordinary domestic and laboratory animals to influenza infection, and the difficulties of securing non-immune human volunteers and inoculating them with a freshly isolated virus during an epidemic period, are some of the factors that make the bacteriological investigation of influenza peculiarly arduous and complicated. The most recent extensive study of which I am aware is that carried out by Falk and his associates in the University of Chicago. Their results, obtained by monkey inoculations on a large scale, are in a high degree suggestive of the isolation of a definite microbe. Their conclusions must necessarily run the gauntlet of confirmation by other workers.

4. Much of the early uncertainty about the identity of inter-pandemic influenza has now disappeared. The careful clinical and epidemiological studies made since 1919 have left little doubt in the minds of most observers that such outbreaks as those of 1920, 1926 and 1928-1929 in this country, and those of 1922, 1927 and 1928-1929 in Great Britain, are definitely comparable with the great pandemics. While we must wait on substantial bacteriological knowledge for a final conclusion, we seem at the moment amply justified in the assumption that at least under modern conditions of transportation there is no break in the continuity of influenza infection in large population aggregates.

Since 1919 there have been many local flare-ups in Europe and North America, and a considerable number of fairly widespread outbreaks in addition to the notable epidemics already specified. This may be taken as support for the view that the virus of influenza is widely disseminated throughout the civilized world; that from time to time special varieties of this virus arise by unknown biological processes; and that some of these varieties become the prime factor in the genesis of epidemics of greater or less magnitude. It may

even be true that these new types of influenza virus are merely immunologic races similar to those known to occur in several familiar microbic groups, and that the advent of one of these new races in a population already fairly immunized to its own indigenous strains finds such a mass of specifically susceptible individuals that rapid epidemic spread is possible. Whether this is the explanation or not, it seems to be the case that at least in recent years influenza has not died out completely on the great continents in the periods between the pandemics. The relatively incomplete data available for 1890 to 1918 appeared to indicate this quite strongly; the observations made since 1918 bear witness that for every calendar year since the greatest of pandemics it is possible to obtain a record of the excessive prevalence of influenza somewhere in the world.

5. In the field of prevention little real progress has been made. It seems justifiable to increase the emphasis already placed on the influenza patient as a definite focus of infection and to adopt reasonable measures to reduce crowding and direct contact to a minimum during a period of epidemic prevalence. A stricter isolation of influenza patients will probably some day be put into effect. During the 1928 epidemic at the University of Oregon,² stress was laid upon the early isolation of all sick persons, with the result that the morbidity was less than 15 per cent, whereas 9 of the 15 nurses employed (60 per cent) contracted influenza. The opportunities for self protection by individuals lie along the same line: avoidance of crowds and of direct contact with influenza patients and with all persons suffering from "colds"; rigorous abstention from the use of common drinking glasses, common towels and the like; and scrupulous hand washing before eating. While measures of personal hygiene designed to promote physical vigor and well-being are assuredly not to be decried, it is not clear that such measures are efficacious in preventing influenza infection during an epidemic period.

In the lack of any demonstrated causal agent of influenza it is plain that no valid specific vaccine is available. The so-called influenza vaccines and serums prepared with a gay assortment of organisms of conjectural importance could hardly be expected to be very effective. In point of fact their use, whenever accompanied by adequate controls, has signally failed to show any beneficial result. In a recent report by Sir George Newman, Chief Medical Officer of the British Ministry of Health, the records of influenza incidence among the inoculated and uninoculated pupils at a large public school from 1920 to 1929 manifest in a striking way the absence of any cogent evidence of protection. Since the immunity conferred by a natural

attack of influenza is apparently slight and transient, we are perhaps not warranted in entertaining very high hopes of success from artificial immunization.

Among the almost innumerable problems concerning influenza that present themselves to the investigator, only a few of the more crucial can be mentioned here.

1. Interest has always been keen in the relation of influenza to the common cold. Observers have reported that during an influenza epidemic many "colds" are of the "influenzal" type, and in some instances definitely traceable to cases of "true" influenza. In a non-influenzal period even, many observers have been struck by the similarity to influenza both of individual cases of "cold" and of small epidemics. There is obviously chance for confusion here, but if it is true, as it seems to be, that influenza never quite disappears from our great communities, it may be fairly supposed that certain more or less definite clinical and epidemiological types deserve to be included in the influenza concept.

One of the most important questions to be settled is: When is a cold a cold, and when is it influenza? The recent studies of van Loghem² in Holland are thought by him to indicate an epidemiological differentiation between the illnesses in that country reported by volunteer lay observers as colds and those reported as influenza. Whereas the increase and decrease of colds in the Netherlands from September, 1925, to June, 1926, ran parallel to the fall and rise of air temperature and, in his opinion, gave no evidence of contagiousness, the reported cases of influenza followed a generally independent course and attained their maximum in March-April. Both pneumonia mortality and influenza mortality concurred with the influenza cases of the inquiry. This is interpreted by van Loghem as indicating a rather sharp demarcation between colds—which he classes as non-contagious commensal infections founded on a disturbance of thermo-regulation—and influenza—which he regards as a true parasitic infection, taking its own epidemic course. van Loghem's data, however evaluated, should be greatly extended to elicit the true relation between colds, influenza and pneumonia. There is obviously much to be hoped here from significant epidemiological studies such as those being carried out by Frost during interpandemic periods.

2. Attempts to identify influenza or to distinguish between influenza and colds bring up sooner or later against the time honored problem of the clinical differentiation of influenza. That this is a hard nut to crack cannot be doubted. Apparently most cases of influenza, particularly those in patients ill enough to be available for

inquiry, are complicated by secondary or concurrent infections with a variety of microorganisms, and the simple influenza symptom complex—if there be such—is consequently usually distorted or at any rate variously colored.

In other diseases clinical phenomena often fail to give clear-cut distinctions corresponding to the specificity of the attacking microbe. Even in well known and long studied diseases, such as typhoid and the paratyphoid infections, clinical differentiation may completely fail. When all is said, however, I am unwilling to believe that the possibilities of clinical study of influenza and colds have been exhausted. Several good observers consider the blood-picture of influenza with its frequent leukopenia, its absence or nearly complete absence of eosinophils and blood platelets and its relative lymphocytosis to be highly characteristic. In the latest epidemic the hematologic picture where observed was said to be strikingly uniform. Intensive clinical and laboratory study of selected cases should be of great value.

3. The significance of local variations in the prevalence and mortality of influenza offers a problem of engrossing interest. Why is it that in definite geographic areas in every great epidemic the discrepancy between the lowest and highest incidence and the lowest and highest excess mortality rates should be so great as is the case? It is stated that in last winter's outbreak in the United States, influenza first appeared in October at San Francisco, where an increase in the death rate was manifest toward the end of the month. In that city, however, the increase in deaths from influenza and pneumonia never reached a high point and the cumulative excess annual mortality rate was only 762 in 11 weeks, while in Los Angeles it aggregated 5,136 in 12 weeks. This was reversing the conditions observed in 1920, when San Francisco had a much greater excess death rate than Los Angeles. It might be tempting to cast about for an explanation of such phenomena on the basis of population immunization, were there not a considerable number of instances in which a high or a low influenza-pneumonia mortality recurs steadily in one and the same locality, epidemic after epidemic. Pittsburgh affords one of the most remarkable instances of this sort, having had the highest—or nearly the highest—rate in any American city in 1918, repeating this record again in 1920 and ranking second only to Birmingham, Ala., in 1929.* The city of Sheffield, England, seems to be similarly liable to frequent and severe visitations of influenza. Of the latest epidemic (1929) the report of the British Ministry of

* It is, of course, impossible to say what proportion of the excess mortality is due to a high influenza incidence rate and what proportion to a high case-fatality.

Health says: “. . . as in previous inter-pandemic outbreaks, this city [Sheffield] appeared to be a local focus of infection.”

A singular feature of local distribution is the patchy character of most of the large outbreaks; cities close to one another often show a marked difference in death rates. In 1928–1929 Cincinnati and Columbus, O., had considerably higher rates than Cleveland and Toledo in the northern part of the state. Dayton, however, less than 60 miles from Cincinnati, had the lowest rate of any of the five cities. In this same epidemic, also, the cumulative excess death rate (9 weeks) was more than 25 per cent greater in St. Paul than in Minneapolis. In April, 1926, the city of Glasgow, Scotland, suffered severely from an influenza outbreak, while Edinburgh, less than 50 miles from Glasgow, was hardly affected by the epidemic and showed no rise in general death rate. It was noted in Massachusetts in the 1918 epidemic that “the incidence of the infection varied widely and for no apparent reason. . . . Marlborough, surrounded by cities and towns almost overwhelmed by the outbreak, had few cases and needed no help.”

Here must be mentioned, too, the change in the general character of an epidemic as it passes from one region to another. The 1928–1929 epidemic in the United States, which first appeared on the Pacific coast and travelled generally eastward, seems to have lost its epidemic push as it neared the Atlantic seaboard. The death rates in New York, Boston, Philadelphia and Baltimore were relatively little affected by the advent of the epidemic. In Germany, on the other hand, the epidemic which first appeared at Breslau about the middle of December, 1928, became much more serious as it travelled westward, the death rates in many towns in western Germany which were attacked a month later rising to twice the height of those of the towns in Brandenburg and Saxony.” Light should be thrown on some of the problems of this nature by the epidemiological studies now in progress of Rosenau and his associates in Massachusetts and of Smillie and others in isolated communities in several well selected parts of the world.

4. One of the most striking features of interpandemic influenza is its seasonal mortality. While it is true that several of the large pandemics have originated in summer, late spring, or early autumn, the majority and especially the minor epidemics of the interpandemic periods have shown—as judged by mortality—a marked predilection for the colder months of the year. In the large cities of the United States the weekly excess mortality rate (annual basis) reached its peak in 1920 in the week ended February 14, in 1926 in the week

ended March 27, and in 1929 in the week ended January 12. In England also, during the outbreaks of 1922, 1924, 1927 and 1929 the peak of influenza deaths in the large cities fell in the first three months of the year.

Continuous morbidity studies accompanied by climatic data should help to determine to what extent the seasonal exacerbation of the influenza death rate is due to an increased prevalence of the infection and to what extent to a relatively high case-fatality. Here also detailed and sufficiently prolonged studies in isolated communities as well as in centers of population are needed for the determination of the fundamental relation between predisposition and infection. There is little doubt that our knowledge of influenza can be greatly extended by systematic epidemiological inquiry along these lines.

Traveling Child Health Centers in Italy

CHILD health centers have been functioning for years in the larger cities of Italy, but they were practically unknown in the rural districts until 1927 when they were organized in these districts by the government. For this purpose it was planned to divide the country into a number of districts each to be under the supervision of a physician and each to be equipped with several traveling child health centers. The number of centers is gradually increasing. So far they have been established for the most part on the islands and in southern Italy. Only one center has been functioning in the North. Each of the centers now functioning serves about 20 rural settlements, 2 to 3 of which are visited in a day. In this way every settlement is visited once each week.

The staff of a traveling center consists of an especially trained physician and one or more assistants. The physician examines mothers and children, tells them the important rules of hygiene and dietetics, and distributes milk and other food for the children. The assistant visits the home and teaches the mother how to dress, bathe, and give general care to the children. Some of the centers have on the staff a specialist in obstetrics and gynecology, who examines the mothers and gives them the necessary advice. A record is kept of every woman and child examined so that it is possible to follow up the cases.

Typhoid Fever Epidemic Occurring During the Summer of 1928*

WILLIAM C. HASSLER, M. D., PH. G., F. A. P. H. A.

Health Officer and Executive Officer of Public Health, San Francisco, Calif.

DURING the past 26 years San Francisco has experienced 3 outbreaks of typhoid fever traceable to milk. The first occurred prior to the earthquake and fire of 1906, and the second during the summer of 1908. In both instances the cause was an acute case of typhoid fever at the producing dairy and came to the attention of the Department of Health through the reporting by the physician of the case after it had been hospitalized. It was not until 10 days later that cases of typhoid were reported in different sections of the city served by these two raw milk dairies. Subsequent to the removal of the patients and the general sanitation of the dairies the situation cleared up.

The outbreak of 1908 resulted in agitation for and, in 1910, the adoption of a pasteurizing ordinance which has since been continuously in force.

The third outbreak occurred during the summer of 1928, and came as a complete surprise because the water supply is carefully supervised and chlorinated, and, except for certified and guaranteed milk which represents but 0.5 per cent of the 52,000 gallons daily distributed, all bulk milk is pasteurized. The process and machinery, thermometers and the pasteurized milk are carefully checked each week.

Except as above stated, no typhoid fever has occurred as a result of milk or water pollution for more than 20 years. San Francisco has always a number of cases of typhoid fever reported (see Figure I for 1928), but the source of infection has been traceable to water or other causes outside of the city and county.

The first intimation of infection in the 1928 outbreak came in May, when 4 cases were reported with a history of having been infected in San Francisco some time between the middle and latter part of April. At the time, a number of instances of diarrhea and bowel disturbances had been reported by physicians, but nothing definite was obtainable

either from stools or urine to indicate that these were of typhoid origin. The department immediately checked on all the reservoirs supplying water, the pasteurizing plants, some 17, that were distributing milk in the city and county, and examined stools and urine from employees in these plants during the month of April.

In order to secure full coöperation of all health agencies, several conferences were held with federal and state authorities, the water company officials, and the milk and produce distributors. The reason for these conferences was the fact that after what seemed a careful survey of the water and milk supplies and the personnel of the pasteurizing plants, with negative findings, the report of cases continued.

There were a number of misleading circumstances surrounding the epidemiology of this outbreak. First, the age incidence was unusually high, 60 per cent (39 cases) occurring between 20 and 45 years—the active working age groups who drank milk with their lunches, which

FIGURE I

FIGURE II

AGE DISTRIBUTION—1928

had been pasteurized by one plant and sold directly from lunch wagons or neighborhood stores (see Figure II).

In Figure III it will be noted that 43 cases used milk from one of three sources. These three pasteurizing plants, located in different sections of the city, are under one management. Plant A, however, is the wholesale distributor to groceries, delicatessen stores, hotels, restaurants and lunch wagons where the cases were particularly concentrated. Plants B and C distribute only to family trade, but when short draw on plant A, a factor which later proved that the source of infection was plant A.

Figure II shows that there were only 14 cases under 14 years of age, the group that consumes the major quantity of milk in its dietary, and while 4 cases obtained their milk from three other dairies, additional milk was purchased from neighborhood stores, and these were supplied from plant 1.

Second, if the epidemic was due to milk, why were there not more cases? Figure I shows no cases in April, 26 in May, 7 in June, 15 in July, and 12 in August. The explanation must rest on the fact that at no time did the carrier pollute the entire supply on any one day, but only those bottles where the capping machine failed to function, and he dug out the faulty cap with his fingers and replaced it by hand. Another interesting fact was that when plants A and B needed extra

No Case had more than two sources of supply.

The amount of milk sold by Plant A was 8,000 gallons daily, by Plant B 11,000 gallons daily, and Plant C 3,500 gallons daily.

The total milk supply of the city is 50,000 gallons daily.

milk it was always taken from the morning batch, which was directly under the care of the carrier, and it was also this milk that went to the stores and lunch wagons. The night pasteurized lot went to hotels, restaurants, and bakeries, and not a single case could be traced to milk obtained from these sources. This information came out only after the carrier had been removed from the plant, and in the effort to check up on the reason the epidemic was not more widespread.

The personal history of this carrier developed that he was unclean in his habits, and when necessary to use toilet he failed to wash his hands, although every facility was available, which I believe explains why only that portion of the supply was infected on which he replaced

caps, coupled with the further fact that his stools were not at all times infective. What might have happened if he had capped all bottles by hand, as is done in some small dairies, is a question.

Third, the peculiar distribution of the cases as to the water supply, and an apparently unusual number of cases of diarrhea and bowel disturbance, justified the assumption that, in spite of chlorination, water was causing our trouble, and it was only later and after intensive study that water was definitely ruled out.

Each day the milk chart emphasized the fact that the milk of one plant harbored the infective agent, but, as stated, these facts came only after painstaking and intensive study of the situation.

WATER

An almost uniform occurrence of the earlier cases in the Laguna Honda Reservoir distribution area led to a careful study of this situation. This work might well be considered first, though the milk, vegetable and shellfish investigations were being carried on simultaneously.

The Spring Valley Water Company owns the water system of San Francisco. Its distribution is by three main supplies:

1. University Mound, a combination of waters from Crystal Springs and Alameda County sources, supplying the low area districts of the city, and comprising the principal commercial section, including heavy and light industrial districts, the financial district, the main hotel district and the residential section. The population of this supply is 260,000.

2. College Hill, a combination of waters from Crystal Springs, San Andreas and Alameda County sources, supplying the central section of the city, and comprising the light commercial and residential districts. The population of this supply is 80,000.

3. La Honda, one-half College Hill and one-half Lake Merced water. (La Honda water is sub-divided into Daly Hill, that part distributed before it reaches the Lake Honda Reservoir, and that which has passed through the Lake Honda Reservoir.) This supply reaches the higher levels of the city and comprises light commercial and better class residential districts. The population of this supply is approximately 320,000.

The cases considered were divided as follows: University Mound, 15 cases; College Hill, 6 cases; and La Honda, 41 cases.

Of the La Honda group, 12 were in districts supplied by this water before it reached the reservoir, and 29 after it passed through the reservoir.

Numerous tests were made of the La Honda water as well as that of other reservoirs. No faulty specimens were obtained from this reservoir, but from the following distributing reservoirs one specimen from each proved to be below the U. S. Treasury Standards, in that they showed the presence of *B. coli* in three tubes out of five tubes of 10 c.c. each.

The Francisco Reservoir (University Mound Water)	July 14
Lombard Reservoir (La Honda Water)	July 17
Potrero Reservoir (La Honda Water)	July 17

All the other reservoirs, and these same reservoirs at other times during the investigation, gave favorable samples. Water was taken daily from 98 different locations throughout the city, and 22 samples showed water not up to U. S. Treasury Standards. We must consider

the tap fouling of some of the specimens. Two specimens were from College Hill sources, 9 from La Honda, and 11 were from University Mound.

The three main reservoirs of the above sources are open, but protected from animal pollution. With the exception of Lake Merced, the main reservoirs have wires stretched across them which prevent pollution by sea-gulls. The smaller distributing reservoirs all have roofs over them. All waters, prior to entering the main reservoirs, are chlorinated. Laguna Honda is chlorinated upon leaving Laguna Honda Reservoir. During the epidemic chlorination was required daily at the outlet of all main and distributing reservoirs.

In addition to this and to check our city water supply, samples were taken from 5 wells, 1 in a milk plant, 1 in a club, 1 in an orphan asylum, and 2 in business plants. The first 3 were below the U. S. Treasury Standards and were ordered closed. The water at the milk plant which was positive for colon bacilli on July 2, cleared up later.

Six kinds of bottled waters were analyzed, and one was found not to comply with the standards and its sale stopped. None of the patients had used this water, so bottled waters were eliminated.

Samples of the ice supplied by the various companies to householders, restaurants, etc., were examined, and found to be excellent.

Three patients gave history of using 3 different swimming pools in

FIGURE IV

ONSET DATES—1928

this city. The routine tests of these pools showed them to be in excellent condition.

FOOD

It being the season when strawberries were coming, the physicians for a time placed the blame upon this fruit, because nearly the entire supply is raised by Japanese and Chinese who were charged with using sewage for irrigation and as a fertilizer; but a careful check of the ranches where the berries were grown, and the market showed no pollution. Oysters, shellfish, and other similar articles of food were investigated, and eliminated because of negative findings.

MILK

Early in the outbreak a careful survey was made of the pasteurizing plants, and all were found to be functioning properly. None of the cases were users of certified or guaranteed milk.

The cases, however, continued. Water and milk were then subjected to a more intensive study that definitely eliminated water, but pointed to a subsidiary plant of one of the large milk distributing depots; so it was determined to make a second examination of the employees of this particular plant. To make sure that none should escape, or substitute another's specimen, the tests were made in groups of 5. Each group was required to enter the Outpatient Service of the Municipal Hospital. A vigorous laxative was administered and specimens of stool were collected by the doctor in charge. One sample was sent to the State Hygienic Laboratory and 1 to the Department of Health Laboratory.

The state found what it believed to be a carrier in a man engaged as a truck loader. Our own laboratory could not confirm this but found a positive specimen from a man engaged on a bottle-capping machine. Both of these men were immediately removed from duty, and taken to the Isolation Hospital where they remained nearly 4 weeks, during which time repeated specimens were secured. The bottle capper gave positive stools consistently, and the truck loader, even with most vigorous laxatives and drainage of the gall bladder, gave negative results. He was released from custody but removed from the milk plant. The bottle capper was released after signing a statement prepared by the State Board of Health agreeing not to engage in milk work or the handling of food stuffs.

Neither of these men gave a history of having had typhoid fever. The bottle capper had been employed for 2 years preceding the outbreak. His removal from the dairy ended our outbreak. That this case escaped attention on the first examination brings out two impor-

tant facts frequently overlooked in field work: The organism may lose its vitality in old feces of constipated persons, but shows in numbers when these individuals take a physic; therefore, the suspected person should be given a thorough cleaning out before taking specimens of stools. Further, where cases can be traced to a dairy, even though results be negative at first, second and third examinations should be made, as carriers may be quiescent for a time, then become active and a menace to life and health. This carrier was the cause of most, if not all, of the 62 cases, 12 of which terminated fatally.

FIGURE V

This milk-borne epidemic is 1 of 8 instances in the United States where infection occurred subsequent to pasteurization. An analysis of the 17 milk-borne outbreaks charged to pasteurized milk shows that in 3 instances raw milk was substituted after pasteurization had been completed; in 3 the milk had not been pasteurized properly; in 2 was heated in a starter can; in 2 there were faulty equipment and faulty flash methods; and in 7 information was not obtainable. The conclusion is that pasteurization was not at fault in any of the 8 outbreaks, but that through the medium of a carrier, the milk was infected at some stage of bottling or handling of the finished product.

AIMS AND PURPOSES

The aim of every health officer is to create safeguards and conditions that will prevent milk-borne typhoid fever infections. How this can best be done is still a subject of controversy. The preponderance of evidence is that the pasteurization of clean milk by employees of known health will eliminate this menace. Where pasteurization has failed in the past, the fault lay in improper methods, or in not knowing the health of those who handled the product after processing.

The purpose of the pasteurization of milk is to make clean milk safe for the consumer, and not to make dirty milk clean, or its contamination inert. The argument of some pediatricians and general practitioners that raw milk is better than pasteurized for infants and children because the vitamins are destroyed by pasteurization has been repeatedly disproved. By pasteurization* we mean the heating of all portions of clean milk to a temperature of not less than 140° F., nor more than 145° F., holding it for 30 minutes, then rapidly cooling the product to 50° F. or lower and putting it in sterile bottles.

CONCLUSIONS

1. The almost uniform occurrence of the earlier cases in the Laguna Honda reservoir water distribution area justified the active steps taken to study this water supply.

2. The small number of cases in children among the earlier groups pointed away from milk-borne epidemic.

3. The outbreak occurring simultaneously with the advent of strawberry season justified the slight suspicion that strawberries might be the source of infection.

4. The department was satisfied that upon the first indication of numbers of cases having their milk supply from the Riverdale plant, the cause lay in this plant, and began taking stools and urine of employees immediately. The fact that the carrier who is considered the responsible person was required among the very first to submit a stool, which was found to be negative, though the later stools proved positive, shows that even at that time the epidemiological work done would have solved the problems, but for a possible fault in laboratory or administrative technic.

5. The epidemic could not be charged to faulty pasteurization, but to a carrier handling the finished product.

6. The importance of knowing that all persons engaged in handling or processing milk are free of communicable disease, and that examinations attesting this fact shall be made not less than once each year, is manifest.

7. All milk, not excepting even certified or guaranteed, should be pasteurized before distribution to the consumer.

First Aid Cabinet of a School Nurse, Her Standing Orders for First Aid, and Her School Nursing Procedure*

CHARLES CHRISTOPHER WILSON, M. D.

Director of Health, Public Schools, Evansville, Ind.

IT would appear that there should be two parts to this paper, one dealing with the nurse's equipment and first aid activities and one with her other school nursing procedures. They can be discussed in a related manner if we consider both the first aid and other activities from the viewpoint of the school nurse as an educator.

All public health workers must be educators, but the school nurse has particular responsibilities along this line. She is working with an organization which has for its goal the preparation of children for life, through the processes and activities we call education. The leaders of this organization, the superintendents and principals of schools, have proclaimed by means of individual statements and through committees of their national organization that their first objective is the health of the child—present and future. To help them realize this objective there are school nurses and school physicians. The nurse, working with our educational institutions, and frequently employed by them, must consider herself an educator, and take advantage of every opportunity to increase her knowledge of educational aims and to increase her skill in educational methods.

The nurse is not always at the school building when first aid treatment is needed, and children will have accidents away from the school; consequently it is desirable that teachers and pupils be taught how to take care of the minor accidents that occur in school or on the playground. Every case that comes to the nurse should be considered by her as an opportunity for education in the principles and methods of first aid treatment. The interest of the child is aroused and he is anxious to know what to do and how to prevent further trouble. The hows and whys of the treatment should be explained in words that can be understood by the child. Perhaps the most important explana-

* Read before the Public Health Nursing Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

tion that the nurse can give is in regard to the application of, and the need for, sterile dressings. There are still many children and parents who do not realize the danger of infection being carried into cuts and abrasions from outside sources and from soiled cloths put over wounds. They should be taught that cleaning a wound and keeping it covered with a sterile dressing are the most important factors in its healing—more important than the application of various kinds of ointments.

Although words are needed for explanations, much is taught without words. The nurse should watch her technic carefully, and realize that her methods will be imitated. She should realize that her reaction to the case will affect the child's attitude in regard to its care and prognosis. She should exhibit a sympathetic attitude, taking care not to exaggerate the importance of slight injuries, while urging the proper care of serious ones without alarming the child.

What are the principal conditions which the nurse will be asked to treat? The majority of cases will be cuts, bruises and abrasions resulting from falls on the playground or in the school building. There will be cases of toothache which the child will expect to be relieved immediately. There will be cases of foreign particles in the eye. Besides these, nurses are also called on to treat, or to teach the mother to treat, cases of scabies, impetigo and pediculosis.

What materials should be kept in her first aid cabinet to treat these conditions? The following list is adequate:

Tongue blades	Ammoniated mercury	70% alcohol
½ and 1½ inch roller	ointment	Zinc oxide ointment
bandage	Adhesive tape	Green soap
Absorbent cotton	Thermometer	Aromatic spirits of am-
Mercurochrome solution	Scissors	monia
Tincture iodine	Medicine dropper	Boric acid solution
Oil of cloves	Paper towels	

When called upon to treat certain conditions, the nurse will need a supply of sulphur ointment, bichloride tablets or kerosene. It is not necessary, however, to keep these materials in her first aid cabinet.

Standing orders in regard to treatment may best be outlined according to the various types of cases:

Cuts and Abrasions—Clean the wound thoroughly. Cleaning is the most important first aid measure. The area may then be swabbed with mercurochrome, a dry sterile dressing applied and held in place with a roller bandage.

Toothache—The nurse should see that every child who is sent to her on account of a toothache makes an appointment with the dentist, preferably with the family dentist; but if the family is unable to afford such services the child should be sent to a dental clinic or school den-

tist. The nurse should see that the appointment is kept. Teachers and parents should be made to feel that a child with an aching tooth has been neglected. Attention and regular dental examinations will eliminate the nurses' toothache problem. First aid treatment consists of removing particles of food from the cavity and inserting a pledget of cotton saturated with oil of cloves.

Foreign Particles in the Eye—Foreign particles located on the eyeball or the lower lid are readily seen and may be removed by gently touching them with a piece of cotton on a toothpick. If a cinder, or other particle, is on the upper lid, the lid must be everted before a good view can be obtained. This is not difficult and practice will develop a skill that permits one to evert the lid with little or no discomfort. After the particle is removed it is well to wash the eye with a solution of boric acid. In removing a foreign particle the nurse should touch the particle with the cotton pledget very gently. If the object is not readily removed, the nurse should immediately refer the case to a physician.

Impetigo—This is contagious and children with impetigo should be excluded from school. The treatment consists of thorough cleaning, including removal of all crusts, followed by the application of an antiseptic dressing, as ammoniated mercury ointment.

Pediculosis—The parts affected should be vigorously scrubbed with soap and water, then thoroughly washed with a 1-500 solution of bichloride of mercury or with kerosene. The ova which are killed by this treatment may be loosened from the hairs and removed by washing with vinegar or 5 per cent acetic acid. The clothing should be carefully examined and if infested be sterilized. Children with live pediculi should be excluded from school.

Scabies—The treatment of scabies needs to be undertaken in a systematic manner if it is to be effective. The ointment frequently recommended consists of 4 parts of lard to 1 part of powdered sulphur. This is smeared over the body for three nights, and followed each morning by a warm soap bath. Clean clothing should be put on each morning, the soiled clothing being thoroughly cleaned.

Many school health departments have forms on which are printed directions for the treatment of scabies and pediculosis together with the drugs to be used. These forms are very convenient and save the nurse considerable time.

It will be well to state what conditions the nurse may treat and what her general policy should be in regard to treatment. As a general policy I suggest this: A school nurse should not accept responsibility for the treatment of any condition—she may treat cases on

orders of a physician when he assumes the responsibility, but otherwise her activities are to be limited to first aid. All cases requiring treatment should be referred to the family physician or clinic physician and, regardless of the need of any individual case, the nurse should not treat it except on instructions from a physician. In some school systems the school physician will give nurses general instructions as to the treatment of scabies, pediculosis and mild cases of impetigo which have been neglected. In such instances, the responsibility is the physician's, even though he does not see the case.

Pediculosis may be considered an exception to this general policy. I can see no objection to the nurse undertaking the treatment of this condition.

Cases of scabies, impetigo and pediculosis are associated with a lack of cleanliness of the body and of the clothing. Every case is an opportunity for instruction in personal cleanliness. It is not one child that has to be instructed, but the whole family.

First aid work and minor treatments are important parts of the school nurse's duties, but they should occupy but a small portion of her time. The success of a nurse in her first aid work is not measured by the number of cases she treats, but by her proficiency in teaching older children, parents and teachers to take care of these conditions. As she is able to do this she will have more time to devote to more important duties, such as classroom inspections and home visitations.

Classroom inspections are a valuable part of the nurse's activities. Their purpose is to detect the presence of any signs indicating the onset of acute communicable diseases, and physical defects that may be remedied. The usual method is for the nurse to stand with her back to the window while the pupils pass by her in line. As a pupil approaches he pulls down the lower eyelid, exposing the conjunctiva. Then the mouth is opened and the head thrown back, to observe the pharynx, tonsils and teeth. Pupils are asked to show their hands, palm and back, with the fingers spread. The skin of the hands, arms, face and neck is thus exposed. The hair is inspected for the presence of pediculi.

By such an inspection the nurse is able to observe some of the common signs of the communicable diseases, flushed face, rash, reddened or watery eyes, running nose, and inflamed throat. She will also notice some children who are urgently in need of dental attention, and some whose tonsils are abnormal. The general appearance of some will lead her to refer them to a physician for further examination. She will take others to the school office or examining room for

a better inspection, for example, pupils whose throats are not visible without the use of a tongue depressor.

When doing classroom inspections, as in first aid work, the nurse is primarily an educator. In the case of inspections, the teacher is being educated, and the nurse's aim is to help the teacher to obtain the knowledge and skill necessary to conduct intelligent and useful health inspections of her pupils. Inspections to detect cases of communicable diseases are of little value unless conducted daily. It is impossible, in any school system, to have a nurse inspect every pupil every morning, but teachers can make such inspections. Most teachers have had no training along this line, and until normal schools supply those who have had such training it will be a function of the school nurse to train them.

On entering a room to make a health inspection, the nurse should acquaint the teacher with the purpose of the inspection and convince her of its value. This may be followed by a statement in regard to the danger of allowing a child to stay in a classroom when in the early stage of a contagious disease. A fact to be emphasized is that the various children's diseases are most contagious in their early stages. Following such an explanation the nurse makes an inspection while the teacher looks on. The nurse carefully demonstrates to the teacher any condition which she regards as a deviation from the normal. At a subsequent visit the teacher may make the inspection while the nurse looks on. Questions in regard to the practice of health habits may be asked at this time. Commendation for children who have practiced the health habits taught, or who have had remediable defects corrected, helps to develop a favorable group attitude.

There are two points requiring emphasis when the teacher is asked to make health inspections. One is that the teacher need not touch any pupil. The inspection is made through the eyes, and the danger of passing an infection from one child to another is eliminated by instructing the teacher not to touch any pupil. The other is that the teacher should not diagnose any condition which she observes. The diagnosis is the province of the physician who is going to treat the case. The teacher is not interested in what disease the child has. She is interested only in determining the presence or absence of any deviation from normal which indicates that the child may be suffering from some acute disease. When she finds such a deviation she excludes the child from school for the protection of the other pupils. The exclusion is not based on the diagnosis of any definite disease, but solely on her suspicion due to changes in the appearance of the child.

The most important duty of the school nurse and the one of greatest value is the home visitation. She may educate parents, pupils and teachers to decrease the need of first aid services, and teachers can develop such skill and experience in conducting inspections that the nurse can be relieved of much of this activity; but none can relieve her of the responsibility and privilege of home visitation. In this work she acts as a correlator of the work of the school and the home in promoting the growth and development of the child.

The first objective in making a visit is a friendly contact with the home, a contact that will help to create in the parent a coöperative attitude toward the activities of school and health officials. Words of commendation or praise in regard to the child will help to develop this. No defect or remediable condition should be mentioned until the nurse has spoken of every favorable condition. Consideration must be given to the point of view of the parent, who should have an opportunity to express her knowledge and opinion of her child. Particularly in regard to protection against diphtheria and smallpox, the nurse must recognize and respect the right of a parent to decide whether or not a child is to receive such treatments. Protection should be urged, and the nurse should give all the facts she can about such treatments, but never in such a way as to antagonize a parent. It means more to keep the good will of an individual than it does to increase by a fraction the percentage of children protected.

Home visits are made for various reasons. Some are to inform parents of conditions in a child that are interfering with his school progress or hindering his proper growth and development. Others are to have the mother consider changes in the school program, it being thought that the child would benefit by omitting some work, or by being in an open window room. Many visits are made for the purpose of talking with parents regarding the health habits of the child and having him vaccinated against smallpox or diphtheria. Regardless of the primary reason for making the home call, there are a few underlying principles that may be followed.

The first is that every child be considered as a whole child, and not as made up of tonsils, teeth, eyes, ears, etc. The immediate reason for making the home call may be to give information regarding clinical facilities for tonsillectomy, but while talking about tonsils the nurse should discuss the child's health from all angles—his nutrition, his practice of health habits, and his behavior. In regard to the latter, the value of mental hygiene is recognized everywhere, and the school nurse should be prepared to advise in regard to mental as well as physical hygiene.

The second is that the nurse consider the family as a whole, and not only the child. Where a generalized public health nursing program is in effect this idea is carried out to perfection, but in many places where nurses do school nursing only, there is a tendency for them to ignore members of the family. A knowledge of the health condition of the father and mother may help to understand better the conditions she finds in the child. The preschool child should receive particular attention.

As a third principle, I contend that every home visitation should be educational, the nurse considering herself as an educator, and her aim the instruction of the parent in regard to the child's condition and the fundamentals of physical and mental hygiene. Regardless of the reason for the visit, the nurse should find the mother in the possession of some health knowledge which she did not have before. When leaving, can the nurse answer "yes" to the questions, "Have I given the parent some ideas that will enable her to care better for the health of her children?" and "Have I helped her to realize that the most important thing that she can do for them is to guard their health?" If she can answer "yes," then her visit has been educational.

My opinion in regard to the status of the school nurse is evident from the brief discussion of three of the important procedures in her program. I regard her as a health educator working with an institution which considers health as an important objective. She is a specialist in child health, and, as such, is capable of advising teachers and parents in matters pertaining to the physical and mental health of children. She avoids duplication of activities that can be taken care of by parent or teacher, and correlates their efforts to develop a nation of strong, robust children.

With this opinion of the status of the school nurse, the standing orders of the school nurse in regard to first aid, classroom inspections and home visitation, may be summarized as follows:

FIRST AID

1. Consider each case referred to you as an educational opportunity.
2. Advise home care of minor accidents which occur at home and after school.
3. Let older pupils learn first aid treatment by doing their own first aid work under your supervision.
4. Accept no responsibility for treatment. (The treatment of pediculosis may be considered an exception.)

CLASSROOM INSPECTION

1. Inspect all pupils as early as possible each semester.
2. Educate each teacher in the methods of health inspection. Plan to super-

vise an inspection which she makes. Impress upon her the importance of daily inspections for the control of communicable diseases.

3. Do not diagnose any condition found.

4. Do not touch children during classroom inspection; if more detailed inspection is needed, have the child report to the office or examining room.

HOME VISITATION

1. Allow nothing to encroach upon the time allotted for visits to homes—it is the most valuable part of your work.

2. Be tactful; avoid antagonizing parents and help them to develop a sympathetic and understanding attitude toward health and school officials.

3. When making a home call consider the child as a whole, and be interested in the whole family.

4. Make every visit a health lesson for the parent.

Sterilization for Human Betterment

THE final summary of the problem, as estimated by Gosney and Popenoe in their book of this title, after studying the results of over 6,000 operations done in a period of 20 years, is conservative but important. No such extensive experiment in this field of endeavor has ever been carried on before. They feel that the experiment has been a distinct success. There have been practically no bad effects; there are rare failures of the operation; the mortality is practically nil, and the results are, presumably, all that could be expected. It certainly tends to prevent the birth of many inferior children, thereby allowing the proportion of superior children born in the population to increase. It also reduces definitely the burden of caring for defectives and dependents.

The program of sterilization for eugenic reasons is usually considered as purely a negative measure, but the authors of this interesting book believe that that is only part of what physicians and others should advocate. There should always be a positive program for the encouragement of good breeding to go along with the negative one of sterilization.—Editorial, *New England J. Med.*, Oct. 31, 1929, p. 893.

Anthrax as an Occupational Disease*

HAVING presented statistical reports at two previous meetings of this section, in 1925 and 1927, on the prevalence of anthrax infection in industry, your committee was asked to report again this year, so that an indication might be had as to the present trend of the anthrax menace.

The collection of reliable data as to anthrax infection has each time presented a difficult problem, and our reports are given with the distinct understanding that they represent an understatement of the prevalence of the infection. We are glad to report that this year we have obtained data from more states than formerly, and more states reporting have been able to give us some definite information as to probable sources of infection, location of lesions, and methods of diagnosis and of treatment.

In 1925 we reported cases and deaths from 15 states over a period of $5\frac{1}{2}$ years. In 1927, 30 states were heard from, reporting for a $3\frac{1}{2}$ -year period, 23 of the 30 reporting one or more cases. The present report covers from January 1, 1927, to July 1, 1929, overlapping the previous one by 6 months. This report lists returns from 38 states, 21 reporting cases or deaths, or both, with 17 reporting no cases. Of the latter, 2 report animal anthrax and infer that human anthrax may have occurred but not been reported. Some states, reporting deaths only, state that as anthrax is not reportable they have no figures as to its prevalence.

Table I lists 162 anthrax cases with 30 deaths, as compared with 222 cases and 25 deaths for the corresponding $2\frac{1}{2}$ -year period in the 1927 report. This is an encouraging decrease in number of cases, but a definite increase in mortality, from 11.27 to 18.5 per cent. Six states reporting cases between 1924 and 1927 report no cases since July 1, 1927 (Delaware, Indiana, Kansas, Kentucky, Minnesota and Virginia); 2 states reporting no cases previously report cases in the 1927-1929 period (Florida and Maine); and 3 not heard from before report cases this time (Arkansas, Oregon and Rhode Island). The tannery states, Massachusetts, New Jersey, New York and Pennsylvania, continue to report cases each year, but only New York shows any appreciable increase. Of the 37 cases reported from that state, 23 were

* Report of the Committee on Anthrax presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

TABLE I
ANTHRAX CASES AND DEATHS IN 38 STATES

STATE	Total for Period		1927		1928		1929 to July 1	
	Cases	Deaths	C	D	C	D	C	D

Total 30 states	162	30	47	10	88	16	27	4
Per cent fatal	18.5		21		18.1		14.8	

C = cases

D = deaths

Blank spaces indicate no report for that year

traceable to wool handling (in the last report Massachusetts had 18, New Jersey 27, New York 29 and Pennsylvania 42).

Table II lists cases and deaths by states and sources of infection, but not by year of occurrence. In 1927, 18 out of 23 states reported one or more cases in which the sources of infection had not been determined, while now only 14 of the 21 reporting list such cases. This is a distinct improvement.

TABLE II

ANTHRAX CASES AND DEATHS IN 21 STATES: BY SOURCES OF INFECTION

January 1, 1927, to July 1, 1929

	Tannery		Wool		Live Stock		Shaving Brush		Horse Hair		Leather		Laboratory Infection		Source not reported	
	Cases	Deaths	C	D	C	D	C	D	C	D	C	D	C	D	C	D

Per cent fatal 14.8	10.8		9.3		33		50		30		0		100		21.6	

C = cases
D = deaths

This table, taken with Table III showing the percentage of cases traced, or untraced in this report and in the previous one, shows a definite shift in the picture of anthrax infection. Forty-six cases are

TABLE III

PER CENT OF REPORTED CASES TRACED TO SOURCE
(based on total of traced cases)

Source	1924-1927	1927-1929	(6 mo. overlap in data periods)
Tannery and Leather	46	36.8	
Wool	28	34.4	
Live Stock	11	16.8	
Shaving Brush	3	0.8	
Hair and Fur	7	8.0	
Professional	2	0.8	
Per cent of cases untraced	52 -	22 +	

traced to tanneries or tannery products, 36.5 per cent as against 46 per cent in the last report. This represents a yearly average of 18+ cases, as against slightly over 19 in the former report.

The 1927 report showed wool an increasing source of infection and prophesied that this increase would continue. In 1925 wool was responsible for less than 3 per cent of the traced cases, in 1927 for 28, and in this report for 34.1 per cent. There were 43 cases, or 17.2 per year, as against 12 per year in the 1927 report. This is a definite increase in cases as well as in percentage.

Anthrax due to animal infection is apparently also on the increase, and we feel sure that the tables understate this increase. In some states, where no other industrial sources are listed, some of the cases not traced were undoubtedly due to infection from livestock. The 1927 report listed an average of less than 5 cases per year traceable to this source, or 11 per cent of the traced cases. This report lists 21 cases so traced, 8.4 cases per year, or 16.6 per cent of the traced cases. Either anthrax from animal contact is on the increase or these cases are being much more often recognized. In the 1927 report only 3 states listed such cases, while in this report 7 do so, 2 others inferring that there were probably such cases unreported where animal anthrax was recognized. Three of four animal source cases in one state (Oregon) were definitely traced to fly bites, the flies acting as carriers from sick animals.

The shaving brush menace, so alarming some years ago, seems to have almost entirely disappeared, as only 2 cases were reported from this source in the 2½-year period. There is little change in the incidence of anthrax from horse hair. One fatal case of infection in a laboratory worker is reported.

The last line in Table II shows the percentage of fatalities in each source group. With a general fatality of 18.5 per cent, that from tannery anthrax is 10.8, from wool 9.3, from untraced cases 21.6, from

horse hair 30, and from animal contact 33 per cent, the last an extremely high fatality from any infection introduced through skin lesions. The high fatality in untraced cases is probably due to the predominance of animal contact infection in this group. This high fatality rate from animal contact cases cannot be blamed on lack of serum treatment, as 5 of the 7 received serum. The high rate for horse hair is based on only 10 cases and may or may not be significant.

This year's questionnaire for the first time elicited sufficient information as to methods of diagnosis, treatment, and location of lesions to allow of tabulation. These data are given in Table IV.

TABLE IV

<i>Diagnosis—where reported</i>		Total Cases	Fatal
Cases diagnosed clinically only		93	7
" " by laboratory		46	10
<i>Location of Lesions—where reported</i>			
Limbs		43	1
Trunk		4	1
Face; neck or head		64	8
Internal		1	1
<i>Methods of Treatment—where reported</i>			
Serum		59	10
Serum and surgery or antiseptics		36	2
Antiseptics or surgery, or both		18	1

Of the 162 cases, 93 were reported as diagnosed clinically, and in 46 other cases laboratory aid was obtained. No data were given for 23 cases.

Types of lesions were classified in four groups: (1) limbs, hands or feet, 43 cases with 1 death; (2) face, head or neck, 64 cases with 8 deaths; (3) trunk, 4 cases with 1 death; (4) one fatal case of internal anthrax from horse hair. These figures agree with the general conception of relative danger. In the remaining 50 cases there was no information as to site of lesion.

Fifty-seven cases were treated with serum alone, with 10 fatalities—5 in those due to animal contact. Thirty-six cases received serum and surgical aid, with 2 fatalities, and 18, 1 of them fatal, received no serum. Treatment was not reported for 49.

SUMMARY

1. An apparent increase in interest in anthrax infection as evidenced by increasing detail in reports, especially as to tracing infection, diagnostic methods, infection sites and methods of treatment.

2. A general decrease in the number of cases reported, confined to tannery and shaving brush infections, the latter being almost negligible. No decrease in infection from horse hair and a definite increase from wool handling and contact with livestock.

3. A comparatively low fatality from tannery anthrax, due to constant watchfulness and prompt intelligent treatment, and an alarmingly high fatality in anthrax from animal contact, possibly due to the rapid spread of many actively growing vegetative bacilli introduced into wounds, as against the longer incubation necessary for the development of the comparatively few spores derived from the handling of hides, skins, or hair.

VOLNEY S. CHENEY

Undulant Fever Germs Hard to Kill

ORDINARY pasteurization methods will not kill the porcine strain of the undulant fever bacillus. This has been demonstrated by Dr. Lloyd Arnold, professor of bacteriology and pathology at the medical college of the University of Illinois and head of the Chicago branch of the diagnostic and research laboratories of the State Department of Public Health, who found that 40 minutes at 140° F. were required to kill the porcine strain of the undulant fever organism.

Whether or not the ordinary milk pasteurization process would so attenuate the bacilli as to render them harmless has not been determined by Dr. Arnold.—*Illinois Health Messenger*, Jan. 1, 1930.

Tests at the New York State Veterinary College have also shown that the abortion bacillus of the porcine strain is not killed by pasteurization at 140° F. for 15 minutes. Experiments on electrical pasteurization by Drs. Huddleson and Carpenter at the Michigan State College indicate that the flash continuous flow method at 160° F. is efficient. In one case, however, the abortus resisted 155° F., though tubercle bacilli were killed.

It is evident that the prevention of undulant fever, especially that caused by the porcine variety of the causative organism, presents a new problem in pasteurization.

Some Difficulties in the Collection of Records*

STEWART G. THOMPSON, D. P. H., F. A. P. H. A.

Director Bureau of Vital Statistics, State Board of Health, Jacksonville, Fla.

THE records discussed in this paper are those secured and maintained in bureaus of vital statistics. The purpose is not to present the discovery of some new method by which records may be collected with entire completeness and accuracy, but rather to start a discussion by the members in our section with a view to an exchange of ideas, thereby bringing about a more sympathetic tolerance for the "other fellow" after viewing the difficulties that must be surmounted before he attains results.

This section brings together representatives of many different institutions having to a certain degree a common interest since the problems affecting one, to some extent at least, affect all. For convenience, let us divide the membership of this section into two groups; those in the first group to include the highly trained statisticians who are equipped to study scientifically and interpret results; the second group to include registrars whose first obligation is the responsibility of securing original records. For many years, I have attended every meeting of our section with an eagerness for more information and new ideas and have gleaned from the papers, discussions and personal contacts, information that has been an inspiration for harder work and more interest in my own department.

We all have our difficulties, we all belong to the same section, and still one member's difficulties are often very remote or unusual to those of another. It is, therefore, with this in mind that I have for a number of years looked forward to a section meeting when a general discussion would bring our members to a better mutual understanding. In my opinion, the splendid work of our special Committee to Aid Completion of the Registration Area, under the leadership of Dr. Dublin, has accomplished a great deal more than the annexing of additional states to the area. It has enlarged the scope of sympathetic feeling between the two groups.

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

One of the greatest difficulties in collecting records is finances. Legislatures should be shown why large appropriations are needed, and, when given, every cent should be spent—wisely, of course, but spent. One of the surest ways to gain recognition is by the judicious spending of money for health purposes. Money in the state treasury may aid in checking an epidemic, but it is far better to prevent the epidemic by spending the money in protecting those who would have suffered.

States and cities with enormous populations usually have financial resources with which to collect and study records. The man highly and technically trained in the science of numbers, even though he has no unusual executive ability, plays a very important part in such a bureau. On the other hand, the outstanding qualifications necessary for the registrar of a state, pioneering in the operation of a vital statistics law, are organizing ability and legal knowledge. If those of our members in the second group can be given inspiration by the results obtained with the records analyzed and studied by the first group, the activities of our section meetings will have an added attraction. In addition to bringing the members of the second group back to the meetings each year, it will stimulate study and intelligent reading, and thereby raise the standards.

A sympathetic understanding of the problems and difficulties surrounding the collection of records is needed if we expect to have a section strong enough to include the interest and enthusiasm of all. Those who have worked in old, established bureaus where law and order hold sway and the doctors and undertakers accept the law as obligatory, know very little about the problems of a pioneer bureau where public sentiment has first to be created before anything like full appreciation of the mandatory elements in the law can be obtained. No one would think of questioning the advisability or value of studying and analyzing to the nth degree, provided the data are complete enough to be representative and the money expended does not unjustly rob the machinery necessary to produce complete records. However, the registrar in a bureau where funds are limited, may become so interested in statistical methods that his machinery weakens, thus causing an irreparable gap in the records with which he is entrusted. On the other hand, there is, of course, the danger of putting all one's time and effort into the collection of records and not polishing the rough diamond which has been mined.

During the past 18 years, I have traveled in practically every county of two states and from personal observations have found conditions that would astonish those who have confined their activities to

thickly populated areas where registration has been going on for many years. The importance of a birth certificate or a death certificate is not appreciated in many localities. In the Vital Statistics Section, we have spent considerable time worrying over what and how much shall be included in these certificates. This is important, but there are many districts where just the securing of a birth or a death certificate challenges the best efforts of a worker. There are still many places where living conditions are such that there is neither a doctor nor an undertaker.

Why worry about the International Classification of Causes of Death when the only information obtainable is that the deceased died from "misery in the stomach"? How can a birth certificate be secured if there is no doctor and the father considers it an insult if you pry into his family affairs by asking questions about his baby? A rare condition affecting the records in Florida last year was caused by the West Indian hurricane. It was not possible in many cases to identify the deceased; in fact, it was not even possible to classify by color, age or sex. Many bodies were not recovered; a great many bodies were cremated in the storm area; and in one instance, 527 bodies were transported in boxes for interment trench-wise. With limited help, flood conditions, decomposition, etc., even a count could not be expected that would represent the loss of life.

Putting a law on the statute books does not necessarily mean that the records provided for in that law will come tumbling into the bureau. On many occasions, I have been met with some such question as this: "It's the law, isn't it?" it being assumed that just because it is a law, 100 per cent of the records should be in the vault. As a matter of fact, the securing of complete records is a man-size job in many bureaus. There are several other laws known to most of us that are not 100 per cent enforced. Law enforcement in connection with the collection of records stands out as one of the important factors in rating efficiency. Our policy has been to make the court a last resort. First investigate all violations of law very thoroughly; give the other fellow the benefit of the doubt in every case; be lenient with those who are ignorant of the law and firm with those who are wilful violators. Study law enforcement in different localities; be firm but sympathetic in the enforcement of the law; and familiarize yourself with living conditions. Where ignorance is the cause of the violation, an educational campaign in that particular district teaching the importance, necessity and usefulness of records, will bring much better results than a hasty prosecution.

The average registrar looks with wonder at the results attained by

the highly trained statistician in much the same attitude that we all look on the radio and airship. Results are often understood by those who are not trained in the method of procedure. Many expert operators of cars are very poor mechanics and in many cases a very efficient mechanic may prove to be a mediocre operator. The statistician should be as familiar as possible with the problems confronting the registrar and his difficulties in securing the necessary records and the registrar should be encouraged and urged to use every available moment in well planned study and work to enlarge his knowledge of scientific methods.

Georgia's Surgical Pioneers

HEALTH Commissioner Wynne adds to its usefulness and extends the interest of his departmental bulletin by incorporating in it brief historical records of, and philosophical reflections on, the art of healing and preventing disease. Recently these included remarks on priority in the use of sulphuric ether to produce anesthesia. These remarks brought from Lamartine G. Hardman, who takes as much pride in his record as a physician and surgeon as he does in the fact that he is Governor of Georgia, a letter of surgical reminiscence which will appeal to the layman as well as to members of his profession.

Governor Hardman recalls the notable Crawford W. Long's pioneer use of sulphuric ether in an operation on James Venable on March 30, 1842, in Jefferson, Jackson County, Georgia. Governor Hardman was largely instrumental in putting up the monument to Long which marks that historic town. On Blackwells Island in 1877 he saw the first demonstration of Sir Joseph Lister's spray utilizing carbolic acid as an antiseptic in operations and for wounds. Sir Joseph's discovery of the potentialities of carbolic acid in control of gangrene is commonly fixed as of 1867. Governor Hardman writes that five years before this, in 1862, Dr. L. A. Dugas of Augusta, Georgia, during the war between the States, used it in the City Hospital where gangrene was prevalent. Dr. Dugas obtained the carbolic acid or the tar water from the pine tar, applying it in all these infections and wounds, and prevented the spread of gangrene. As a student of medicine, Hardman was taught by Dugas in Augusta Medical College. He declares that Dugas "is really the father of antiseptic surgery"; that he was the first to suggest laparotomy for gunshot wounds in the abdomen; and the first to use animal ligature—catgut—in the closing of wounds in the intestines, which he did in Wilkes County, Georgia, in 1856 or 1857. This catgut was a violin string taken from a fiddle at a party; the patient recovered. This incident is not mentioned in the biography of Dugas in *Appleton's Cyclopædia*. As a loyal Georgian, Governor Hardman says that he "suggests these thoughts that America, and especially Georgia, might be placed where they belong in their contribution to the relief and prevention of human suffering." In medicine and in surgery, as in other arts and sciences, establishment of precedence is sometimes difficult; the Doctor-Governor of Georgia is not dissuaded by difficulties from any essay at what he considers proper allotment of credit.—*The Sun*, New York, N. Y., Dec. 7, 1929.

Responsibility of the Public Health Nurse for Social Phases of Her Work*

KATHARINE FAVILLE, R. N.

Instructor in Nursing Education, Teachers College, New York, N. Y.

THE primary objective of public health nurses has evolved during the last 25 years from one concerned mainly with giving care to the sick poor, to that—commonly accepted today—concerned with attaining a maximum of health for all members of each family in the community.

Each year as science opens new ways of removing obstacles from the path of this objective it reconfirms the knowledge that health cannot be secured by caring for physical needs only, but is the result of many factors; that individuals cannot be viewed as entities unaffected by their environments; that physical health and mental attitudes have a direct relationship; that to treat effect intelligently one must search for the underlying cause, often obscure and elusive. Each year brings us to more forceful recognition of the close relationship between the so-called social and health problems of a family, and of the necessity of adjustment of the one if we would better the other.

As the public health nurse works in homes with families she further observes that these social problems which she uncovers fall mainly into two groups—minor maladjustments which if left uncared for may develop into serious social and health problems later; and acute major problems of an easily recognized pathological nature, often the result of lack of proper treatment in the past. The handling of these two groups differs, one calling for preventive, and the other for curative treatment. To facilitate clearer thinking, let us discuss each separately.

RELATION OF MINOR SOCIAL MALADJUSTMENTS TO THE WORK OF THE PUBLIC HEALTH NURSE

Almost every family, if studied, will be found to harbor problems of minor social maladjustment, many of which with time and under-

* Read before the Public Health Nursing Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

standing will right themselves. Others, if left untreated, may develop with the years into acute social ills—such problems, for example, as arise out of wrong attitudes between husband and wife, parent and child, or the child and his playmates. The presence of a person with mental deficiency or mental disease in a family that does not understand the difficulty or know how to handle it may completely wreck that family's chance to attain normal health and a happy life. Bad housing, poor housekeeping, unwise expenditure of an adequate budget, are barriers that keep many a public health nurse from realizing her "primary objective" in countless families.

The father who is ill with tuberculosis will not quickly show much permanent improvement so long as he is deeply worried over family finances, nor can the public health nurse easily safeguard children whose tuberculous parent insists on returning home from the sanatorium for frequent and lengthy visits because he is lonesome. She is learning that it is a much more difficult task to give adequate prenatal supervision to the mother who is unhappy over the expected arrival of the new baby, than to the mother who is joyfully anticipating him, and that she has but begun to understand the significance of the relationship between mental attitudes and physical health during pregnancy. She sees that child hygiene is becoming more and more linked up with parental education; that, for example, wrong feeding habits of children are often corrected only after the mother gains a clearer understanding of her unconscious motives in pampering her child. Again, the underlying reasons and attitudes that result in the uncoöperative patient must be unearthed and understood before much of constructive good can be accomplished with him.

Because of this shift of emphasis in her program and her appreciation of the added responsibilities, the public health nurse has come to change her attitude toward these minor, or incipient, social and mental problems. She has always had these before her, but where formerly she felt that she could not give attention to them because they would take time from an already overloaded program, she now sees that it is impossible to do good health work until they are dealt with, and so, far from jeopardizing her primary objective, such adjustment has become a step toward its attainment.

With this change in point of view, and the increasing demands from the field, it is not strange that nursing education is having to change in an effort to fit the nurse better for the task which confronts her. A beginning is being attempted with student nurses in some of the schools of nursing, who are being taught through use of the case study method to care for their patients, not as isolated cases but as

individuals, part of family and community life, whose illnesses bear directly upon those groups and their adjustments to them. They are being taught that it is impossible to do good constructive health work unless at the same time they see and understand the many social implications of their patients' problems.

Postgraduate courses in public health nursing are requiring their students to take many courses that help to give this broader outlook—psychology, sociology, mental hygiene, methods of family case work, methods of teaching. Never for one moment do we think of turning our public health nurses into "social workers," but we do hope for the nurse with the quickened social conscience, the nurse who sees the full implications of the social and mental phases of her health work.

To meet the needs of the older nurses already in the field, organizations are arranging staff education programs which are constantly widening in scope. A few forward-looking agencies, realizing the need for extensive study of this whole problem, are employing trained mental hygiene workers experienced in case work methods as supervisory consultants to their field nurses, in an effort to see just how much the application of mental hygiene and case work principles will help the average public health nurse to handle her family situations more wisely.

Although these experiments are really just well under way, a good beginning has been made toward the development in the nurses of better attitudes, and easier approaches to the day's work, attempting to increase their understanding and intelligent sympathy, to strengthen their sense of relative values, and to refine their technics in working with families. Study of the work now being done will undoubtedly do much to shape future policies, and should create a most promising field for the specially trained mental hygiene case worker who likes to teach and to accomplish results in her families by working through the staff nurse.

RELATION OF MAJOR SOCIAL PROBLEMS TO THE PROGRAM OF THE PUBLIC HEALTH NURSE

In the course of her work, the public health nurse also meets many problems involving social maladjustments of individuals in her families of such an obviously acute nature as to leave no doubt that the need is for immediate, skilled treatment—the sudden decrease of family income through death or illness, the neglect or mistreatment of children, the need for boarding home care, the problems of illegitimacy, improper guardianship, delinquency, and so on. There can be

no question that it is the responsibility of the public health nurse to sense and evaluate these problems in the homes that she comes into contact with, recognizing that here the question of proper treatment is often closely tied up with that larger one of community resources.

What is the financial rating of the community? Can it provide specialized, trained workers to handle these acute problems? Does it provide them? If it does, then so far as the public health nurse is concerned, the matter is best resolved into one of securing increasingly better coöperation with the social agencies—coöperation which is built on mutual understanding, faith, good will, and a common desire to give the community the best quality of service possible. One public health nursing agency has found that the addition of a mental hygiene case work supervisor to the staff has done much to help the field nurse in referring these problems more intelligently, giving her a better understanding of the social worker's point of view and the difficulties under which she works, as well as a more specific knowledge of what she can fairly be expected to accomplish in a given time.

If no such workers are supported by the community at the time, is it due to financial inability or to ignorance? If the latter, again the public health nurse has an opportunity for public education, working through her board of directors and nursing committees. Countless communities throughout the United States owe the provision for increased social work facilities to the determination and leadership of public health nursing groups and lay groups spurred on by nurses of vision.

There are many rural areas that for years to come cannot afford more than one community worker—cut over timber lands that have to await the growth of new forests for return of prosperity; agricultural sections where banks have failed until almost none are left; regions where the total resources are too poor to support even the most meager of public schools without much federal aid. The health needs of these rural people are often more readily recognized by themselves than their social or mental ones, and the work of the public health nurse carries an appeal—through her service to children—that is often the first to be met. No matter what the need for trained social workers, it has to be admitted that probably in many of these communities they will not be employed out of local funds for several generations to come.

What is the public health nurse to do with these acute social problems?—leave them alone? Some do, and that this is entirely unsatisfactory from a community point of view is too obvious to need comment. Shall she try to solve them herself, adding them to an already

greatly overcrowded program? If she does, one of several things will happen: She may choose to work longer hours than any one human being should, and finally lose courage and leave. She may drop part of her health program to make way for these other very difficult duties, with the result that both health and social programs are poor in quality, but the best that she can give unaided. Some sections have tried this method as a state-wide policy, and after several years of observation have been forced to admit that from a public health nursing angle, at least, it has been unsuccessful—the quality of the health work accomplished has been so poor.

The public health nurse may train a group of lay people to study seriously these community and family needs, handling each problem as it arises as an individual community challenge. The first two methods have not been satisfactory from the community's point of view; this last is still so experimental that little definite advice can be given as how best to train such groups. Certainly the public health nurse needs help here, and we look for the time when travelling field advisers, perhaps mental hygiene workers trained in case work, will be supplied to the rural nurse by such agencies as bureaus of public health nursing of state boards of health, or the American Red Cross, to help in the training of these groups, and to give advice to her on the disposition of her concrete social problems. The whole question, as it relates to these poor rural areas, is one that needs much experimentation, scientifically done, honestly analyzed.

A few agencies, believing that they obtain a better quality of family and community service through use of the combination worker, are advocating the nurse-social worker, who carries all the social and health work done by the organization in her families, much as is being practiced in certain parts of Europe. One notable exponent of this is the New York Association for Improving the Condition of the Poor; but even here need is felt for more experimentation with certain phases of the work, before this organization is willing to recommend the practice unreservedly to others.

From them we hope in time for the answer to some of these questions:

What shall the family case load be for such field workers—smaller, of course, than that of either nurse or social worker who handles but a single phase of the family problems—but how small as a maximum?

What factors must enter into the determination of size of case load?

How shall such combination workers be trained, and where, so that they will be able to practice not only treatment but prevention?

What form shall staff education take to this end? How shall supervision be given, and by whom—an expert in each field, or a combination worker of long experience and complete education?

Is the nurse-social worker more or less expensive to the community, realizing the many factors—of education, supervision, and administration—which must be considered?

What are the concrete, specifically proven advantages to the family and the community of this type of worker over the other two specialists?

Even in such an organization as the A. I. C. P., we find certain phases of both social and health work done by specialists, so that the field workers are not carrying on completely generalized organization programs in all families. Why?

There is one last phase of the subject which will bear brief mention. That is the responsibility which the public health nurse is having thrust upon her in families that are economically self directing. In every community there are many such families who, when trouble comes, rarely think of turning to a specialized social agency for advice and help; but to them the friendly public health nurse has daily access, and to her sympathetic ears are recounted troubles of all sorts and sizes. She feels her obligation to advise as wisely as she can, calling for the assistance of specialists when they are available or necessary—but for years to come it is safe to prophesy that she will be the guide sought more and more by self directing, economically independent families, whose maladjustments and needs are often as acute as those found in the poorest tenement flat.

In conclusion, we can but repeat that this question—how the public health nurse handles the social phases of her health work—needs such careful study as to make experiments with it watched with keen interest by both nurse and social worker, here and abroad. It behooves us individually and as a profession to keep open minds, and to give every encouragement to groups who courageously step away from tradition to try out new methods, to develop new points of view. Let us only make sure, first, that our experiments are scientific in procedure, for opinions based on opinion only without substantiating scientifically collected facts are of too uncertain value to be of much use in guiding programs of work; and, most important of all, let us take care that in our zeal for research we do not forget that primary purpose to which all public health nursing is committed—giving increasingly better health service to families.

How To Tell What*

In Popular Health Instruction

IAGO GALDSTON, M. D., F. A. P. H. A.

New York Tuberculosis and Health Association, New York, N. Y.

THIS title may sound like a barbarism, but there is reason behind it. For several years our section, particularly in its clinics, has devoted much time and effort to the consideration of the content of health education material. Basic rules have been formulated and presented as guides to the selection and evaluation of the data, which might profitably be incorporated in our educational program. Scientific accuracy, soundness of basic fact, appropriateness, pertinence, and the like have been stressed as the *sine qua non* of the material out of which our educational instruments must be fashioned. In direct presentation and through critical self testing we have listed, tried, and affirmed these norms. We have thus thoroughly considered the *content* of the "What" of health education.

These considerations constitute but the first principles in our complicated metier. That sound construction implies good building material, is a valid principle, but it neither defines the technic of construction, nor yet foreshadows the pattern of the ultimate product. It is this part of our problem that we designate by the "How" of our title. It is our aim in this paper to start where we left off a year ago, and advance to the consideration of a few basic principles in the technic of our art. I say "our art," because, as Routzahn stoutly insists, health education deals with science, but is not in itself a science. It is predominately an art, and art is that elusive something which does not lend itself to complete definition, nor can its essence be reduced to principles. Most of us can attest to this fact out of our own experiences. When confronted with a piece of health education material and asked for our judgment, we are like the amateur art critic who begins his critical remarks by the affirmation, "I know little about art, but I know what I like." An effort has been made to reduce this "knowing what we like" to principles.

In all, there seem to be but four cardinal principles to the technic of health education. The technic of a good salesman, when analyzed,

* Read before the Public Health Education Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

resolves itself into four steps: first, he arouses curiosity, then enlists sympathy, gives information, and lastly, by a masterful stroke puts across his sales. These are also the four cardinal principles in the health attraction technic.

Health education material should first and foremost arouse curiosity. Living human beings are bodies in constant motion, following a course determined by antecedent propelling forces. If it is our desire to change the course of human movement to a new direction—toward health consciousness—in conformity with the well known principles formulated long ago by Newton, we must apply a new force to the body in such a way that the resultant of the initial and new force will deflect the moving body toward the desired end. For this there is no more effective agent at our command than curiosity. No thing so readily takes a man off his appointed task, or out of his determined path as curiosity. Watch a man as he walks the street, or a child as it plays. Seldom is the path as straight as the proverbial arrow, rather it zigzags, the point of deflection corresponding usually to where the stimulus, the force of curiosity, has produced a new resultant direction.

Our first step must therefore be to arouse curiosity, to force, if you please, a consciousness of our presence upon the selected subject. But—and this is the second principle—having aroused curiosity, and thereby having secured attention, we must now retain it. To achieve this we must enlist sympathy. A man may be walking, thinking of his stocks or bonds; he becomes aware of the beating of a drum; he turns his head in the direction of the sound and perceives a heretofore unnoticed crowd. His curiosity is aroused; he draws near and finds a revival meeting going on. Whether he remains to listen to the exhortations or goes on his way will depend on a variety of conditions, but in no small measure on whether his sympathy has been enlisted. Curiosity attracts, sympathy holds, and it would profit us to comply with these first two principles in the construction of our health education material.

Assuming we have achieved both; assuming that we have aroused curiosity and enlisted sympathy; what then? These first two steps are but means to ends. What are the ends? The ends of health education are instruction, and action. The third and fourth principles in our health education technic are, therefore, to impart information and to lead to action. These need no elaboration, they are self-evident; hence, we may recapitulate and say that four cardinal principles in health education technic are: (1) to arouse curiosity; (2) to enlist sympathy; (3) to impart information; and (4) to lead to action.

Having enumerated these principles we must consider in a more concrete manner how they may be applied. We must ask and find an answer on how to arouse curiosity, on how to enlist sympathy, as well as on how to impart information and lead to action. The first two of these we will consider in greater detail than the last, partly because they lend themselves to more ready generalization, and partly because they have been less commonly dwelt upon.

How is curiosity aroused? The answer is simple—by the extraordinary, by the novel, by the new. A man standing silently and operating a little machine into which at one end are fed slips of white paper that emerge from the other as dollar bills is a novel sight. He therefore attracts attention. An old proverb given a new twist is novel, and will attract attention. New color combinations, odd patterns, novel forms; these and like agents can be used to arouse curiosity, to attract attention. But, in arousing curiosity, one must not confuse the extraordinary with the sensational, nor the novel with the bizarre. Arousing curiosity is not an end in itself—carried to an extreme it tends to defeat the end which it should serve.

Having aroused curiosity it is our aim to retain attention, and this means enlisting sympathy. How is this to be achieved? The answer is to be found in the vital egocentricity of man. Under each and every circumstance man tends to interpret his environment, and everything new confronting him, in terms of himself and his own. Consciously or otherwise he asks of everything, does this concern me and mine, and if so, how? If it does concern him he is either sympathetic or antipathetic. If it does not concern him he is indifferent, his consciousness moves on to newer fields. If, therefore, we aim to enlist the sympathy of the person whose attention we have secured we must anticipate his question, "does this concern me?" and answer it convincingly in the affirmative.

Having achieved the foregoing we are in an advantageous position to secure the ends of health education, namely to impart information, and to lead to action. The former comprises a field intricate and extensive, and it is not vital to our consideration, or possible now to enter into it in a detailed manner. Its own technics are so multiform and so dependent on the nature of the information to be imparted and the conditions of those addressed, that even to attempt to consider them here would lead us far afield. Only this needs to be noted—that the novel and sympathetic manner of presenting facts will tend to make them more welcome and more appreciated. Our first two cardinal principles integrate with the third.

Finally, there remains to be considered the "How" of leading to

action. The key to this problem is the appeal to the emotions. We may instruct and convince by an appeal to the intellect, but the emotions seem the fountain source of action. Desire is primarily an emotion which, I grant you, most of us as thinking beings tend to rationalize. To achieve an action we must make the end desirable, which means we must emotionalize it, preferably with a pleasurable emotion, though sometimes of necessity with a painful one.

Commercial advertisers have appreciated these various items in the technic of education, and though we may not agree with their ends, we can profit by their methods. Witness for example how the advertiser attempts to sell his five-foot shelf of books. Does he content himself with a mere intellectual appeal on the value of culture? No, he emotionalizes his appeal by promising the purchaser of his commodity popularity with the fair sex, and a spellbinding faculty with the men.

The four cardinal principles in health education technic which we have listed might at first appear like so many water-tight compartments definitely separated from each other. It may be convenient for the purpose of exposition to present them in this fashion, but actually they are not so separate; on the contrary, they tend to integrate and fuse. That which arouses curiosity may at one and the same time enlist sympathy, or even instruction. For our technologic purposes, however, and for checking on our material it is worth our while to test our educational instruments for each of these desired qualities. Thus, when our preliminary work has been done and we have gathered together the material, the "What" of our health education, then it is up to us to attempt its organization in the manner outlined. The substance should be so manipulated that it will arouse curiosity, enlist interest, impart information and lead to action.

Needless to say it is not always possible to accomplish all of these four objectives in every piece of health education material. A poster for example may only arouse curiosity; a piece of literature may do the same, and in addition enlist sympathy, but if the individual piece may not achieve all four objectives certainly the totality of our program or campaign should accomplish this.

Pasteurized Dried Fruits*

CARL R. FELLERS, PH. D., F. A. P. H. A.

Massachusetts Agricultural College and Experiment Station, Amherst, Mass.

IN this paper it is desired merely to discuss briefly certain public health aspects of dried fruits. Tremendous quantities of dried fruits, such as raisins, dates, figs, prunes, peaches, apricots, and apples, are produced either in this country or are imported. They are liberally eaten and relished by people in every walk of life.

The basic principle of drying is the reduction of moisture to a point where microorganisms are unable to proliferate and cause spoilage. For most dried fruits, this moisture content critical point varies from 20 to 30 per cent according to the amount of soluble solids present in the fruit. Naturally the higher the concentration of sugar, the greater the moisture content that can be tolerated without spoilage.

Drying is carried on both by evaporation in the sun and dehydration in stack, kiln, or forced draught tunnels. The latter method is becoming more and more popular and actually produces higher yields of superior quality dried fruits. Rain damage, insect infestation, and spoilage are largely precluded when fruits are dehydrated.

In sun drying, the temperature of the fruit seldom exceeds 120° F. Dehydrated fruits reach temperatures of 160° to 180° F. To avoid case hardening, absolutely dry air is not used for dehydration, but rather air containing 20 to 40 per cent relative humidity. Dehydration processes ordinarily require from 8 to 36 hours for completion. Lye dipping for a few seconds to check the skins and hasten the evaporation of water is usually practiced. Sulphuring, that is, exposure of the fruit to fumes of sulphur dioxide to prevent discoloration, is also generally employed on apples, pears, peaches, apricots, and some kinds of grapes and figs. Normally, prunes are not sulphured. The sulphuring also protects the fruit against spoilage and, according to recent researches, serves also to conserve vitamin C.

Dried fruits are sold both in bulk and packed in retail sealed paper cartons or tins. The use of the sealed paper carton or tin for merchandizing dried fruit is growing rapidly. From a public health point of view sealed packages are to be preferred to open bulk containers.

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

MICROÖRGANISMS ON DRIED FRUITS

Very limited studies have been reported. Prescott,^{1,2,3} working largely with artificially dehydrated vegetables, found a varied microbial flora on dried peaches, tomatoes, bananas and vegetables. The numbers of bacteria varied from less than 100 to over 1,000,000 per gm., with an average of less than 10,000. The types were similar to those found on fresh fruits or in soil and water. Both spore and non-spore formers were isolated. No pathogens or toxicogenic bacteria were found. Saprophytic molds were nearly always present, usually as spores which evidently had survived all pretreatment and dehydration. He found that the numbers of microörganisms on dried foods gradually decreased during storage, providing the moisture content remained approximately constant. Several laboratory and plant tests using fresh vegetables and fruits artificially inoculated with *B. coli*, *B. paratyphosus* A and B, *B. enteritidis*, *B. suispestifer*, *B. typhosus*, *Cl. botulinum*, *Micrococcus pyogenes aureus* and *B. subtilis*, were made with "very reassuring" results. Although no typical pathogen was recovered from the vegetables or fruits after thorough dehydration, the data presented are rather vague and inconclusive.

Nichols⁴ found no sample of dried fruit sterile, but many had only a few bacteria and molds. No pathogens were found. He calls attention to the possibility of contamination between the dryer and the consumer. Though too dry to grow, bacteria may not immediately die but remain dormant until more favorable conditions of moisture and temperature arrive.

Hunwicke and Grinling,⁵ in England, traced an outbreak of severe colitis to French packaged dates. The causative organism is called *B. coli tropicalis*, the description practically paralleling that of *Escherichia coli*. Eleven samples of French and English packaged and bulk dates were examined bacteriologically with the result that intestinal coliform organisms were isolated from six. Strangely enough, none of the bulk date samples showed any intestinal bacteria. It was concluded that dates may readily be contaminated during the repacking process, and that the presence of coliform organisms on the surface of packed dates constitutes a serious public health problem.

EXPERIMENTAL WORK

Inasmuch as the findings of Hunwicke and Grinling in England demonstrated the possibility of disease transmission by dried fruits, certain bacteriological examinations were made in our laboratory of the dried fruits found in American markets. No active spoilage was noted in any sample.

Standard laboratory methods of the American Public Health Association were used. Ten-gram samples of the fruits were placed in 90 c.c. of distilled water in rectangular, rubber-stoppered dilution bottles, shaken, allowed to stand 1 hour, then violently agitated for 2 minutes. Nutrient agar plates incubated at 30° C. for 72 hours were used. Due to overgrowths of molds in some cases, mold counts were made after 48 hours. Some of the data are given in Table I.

TABLE I

MICROÖRGANISMS IN AMERICAN DRIED FRUITS AS PURCHASED

Description of dried fruit	No. of samples	Average moisture content	Bacteria per gm.	Molds per gm.	Yeasts per gm.	No. of samples contg. lactose fermenters

Cranberries, packaged.....	1	6.0	0	3	0	0

Variations in numbers of microörganisms on dried fruits are very great. It is necessary to use the results obtained from several samples if reliance is to be placed on the data. The method of averaging counts as in Table I is subject to criticism. Some samples have no bacteria while others may have 100,000. Obviously it is not exactly fair to call the average count 50,000. Since it is impossible to print individual counts the method of averages is used.

The counts on raw dates are highest of any of the fruits, while sulphured fruits are lowest. Without doubt the length of storage largely determines the numbers of organisms present as Prescott and his coworkers² have demonstrated. It is therefore probable that

some of the samples examined harbored many more organisms after packing than the examination showed. On the other hand bulk dried fruits may readily pick up organisms by improper handling and storage. Of the 79 samples of dried fruits examined only 8 contained lactose fermenting bacteria. None was identified as *Escherichia coli* though several closely resembled *Acrobacter acrogeneris*.

It is surprising that yeasts were not encountered more often. Sixty of the samples showed no yeasts—at least none developed on the nutrient agar used as a medium. This is contrary to the belief that yeasts are abundant on dried fruits. Anaerobes were present in somewhat over half of the samples but always in small numbers. Cocci, especially Sarcinae and Micrococci, were relatively abundant and second in numbers only to the spore-formers. The molds were all common saprophytes. *Aspergillus* was most numerous, with *Penicillium* second, and *Mucor* third. In many samples molds outnumbered the bacteria. The spores of the *Aspergilli* were relatively heat resistant. Some usually survived the pasteurization processes which destroyed all microbial vegetative forms and greatly reduced the number of bacterial spores.

Bulk dried fruits harbored more microorganisms than packaged. There is a strong tendency in the trade toward the package as opposed to bulk goods. The packers are simply catering to the public demand for a clean, wholesome, uniform product.

PASTEURIZATION

Preliminary experiments with dates, figs, raisins and prunes have demonstrated that these fruits may be heated to pasteurization temperatures without injuring their texture or flavor. The total numbers of organisms were greatly reduced. In the case of dates the average reduction varied from 93 to 99 + per cent; prunes and seedless raisins gave similar results; but figs were much more difficult to handle and gave somewhat inconsistent results.

In the case of dates, huge commercial continuous pasteurizers are now in use which handle several thousand cases daily. The process is varied for each type and variety of date but the results have been very encouraging and the process is effective not only in destroying a large percentage of the microorganisms present and thus insuring a safe food, but the appearance, texture and flavor are actually improved. The dates are treated in the retail paper carton and are not handled after the heat treatment.

Numerous laboratory experiments showed that temperatures of from 160 to 185° F. in the fruit at humidities of 70–100 held for from

30 to 90 minutes were effective for the different dried fruits. A usual preliminary or coming-up time of 10–30 minutes is necessary in addition. The moisture content of the original fruit, its size and texture affect the efficiency of the pasteurizing process. It is necessary to work out the individual and combined effects of these variables for the different fruits, and even varieties and grades of the same fruit. There is a slight increase in moisture content of all fruits treated by this method, varying from 1 to 5 per cent, depending upon the original moisture content as well as humidity. Forrest⁵ has been granted a patent on a process designed to recondition prunes and figs which have dried out and sugared. He uses temperatures somewhat below 212° F. for varying exposures. We found that lower temperatures are efficient in pasteurizing the more acid fruits, because of their lower pH. For example, peaches, apricots and prunes can be treated at lower temperatures than figs or dates.

INOCULATION EXPERIMENTS

Only laboratory tests have been made. Dates, figs, raisins and prunes were coated with cultures (2 sources) of *Escherichia coli* and subjected to various pasteurization treatments. In all cases where the relative humidity was 75 per cent or more, a 30 minute-exposure to 160° F. was sufficient to destroy all the organisms. Approximately 40 of these tests were made. Using *Eberthella typhosum* on dates, a single experiment showed complete destruction of the organisms after exposure to 170° F. for 25 minutes, or 160° F. for 30 minutes, at a high (unmeasured) humidity. Since the colon bacillus is considered more resistant than the typhoid, the above findings are significant. In conducting heat treatment experiments care must be taken to keep up good air circulation, otherwise considerable variations in temperature occur in different parts of the pasteurizer. Wet steam forced into the air chamber by means of fine spray nozzles and thoroughly mixed by the use of electric fans, was the method of regulating humidity. Humidity was calculated by means of recording thermometers, giving both dry- and wet-bulb readings.

STORAGE TESTS

A few storage tests were conducted wherein cartons of dates, prunes, raisins and figs were liberally inoculated with *Escherichia coli* and stored at laboratory temperatures until the organisms had died out. Though the results were variable the colon bacillus always died out on prunes in 15 days; and on raisins, dates and figs in 30 days. Prescott, Nichols and Powers⁷ had previously pointed out that the

bacterial count in dried vegetables gradually decreases during storage, providing the moisture is under 10 per cent. Molds remain more nearly constant. There is no doubt that the bacterial and yeast counts of dried fruits which have undergone long storage will be low.

CONTROL OF DEHYDRATED FOODS

Prescott⁷ and the *U. S. Army Quartermaster Regulations* sum up the situation as follows:

After dehydration, fruits and vegetables should be packed at once in suitable tight receptacles or stored in bins which have been specially prepared and which have adequate protection against vermin, insects, molds and other microbic enemies. Such storage receptacles or containers should prevent access of moisture in sufficient amounts to render the food material capable of fermentation or decomposition. The methods of handling the finished product in the factory should be such as to preclude infection of any sort. Care should be taken to impress upon the manufacturer that he is dealing with a food material and that it is essential to the welfare of the consuming public that such food materials should be placed before the consumer in a wholesome and uninfected condition.

Since many of our dried fruits are not dehydrated but merely sun dried, and all are often handled or exposed to infection during repacking or storage, in addition to the above recommendations, at least in the case of some dried fruits, a final heat treatment or pasteurization in the carton should greatly aid in insuring a safe and satisfactory product.

SUMMARY

Dried fruits harbor considerable numbers of molds and bacteria and also a few yeasts. It is desirable to protect the public against bacterial infection from these foods. At least one such outbreak has been reported.

Dried fruits such as dates, raisins, figs, apricots and prunes may be pasteurized in paper cartons with moist heat at controlled temperatures and humidities. In general, different treatments are required for each fruit and often each variety must be handled a little differently. Temperatures which have been found effective in greatly reducing the total numbers of microorganisms on dried fruits at humidities of 70–100 per cent vary from 150° to 185° F. for 30 to 70 minutes. *Escherichia coli* and *Eberthella typhosum* were destroyed in every case where the temperature of the fruit remained at 160° F. or above for 30 minutes at relative humidities of 75 per cent or more.

Commercial processes for the effective pasteurization of dates, figs and raisins are now being developed or used.

Sulphured fruits harbor very few organisms because of the inimical

effect of the sulphur dioxide. Acid fruits are more easily pasteurized than those of higher pH.

From a public health viewpoint, pasteurization marks a definite advance in the merchandising of dried fruits.

National Better Business Bureau

THE National Better Business Bureau, with headquarters in New York, and the various affiliated Better Business Bureaus scattered over the country have for some time been doing excellent educational work in giving editors and publishers the facts regarding schemes that are operated to the detriment of the public. Naturally, the medical field comes in for its share. Physicians may be interested in knowing that not a day passes but the Bureau of Investigation of the American Medical Association receives requests either from the National Better Business Bureau or from some of the affiliated Better Business Bureaus asking for information on certain medical schemes that seem open to suspicion. More than 600 such letters have been received and answered so far this year.

The Better Business Bureaus are primarily interested in "Truth in Advertising." Knowing that every false, misleading or fraudulent advertisement in any field tends eventually to break down public confidence in all advertising, the Better Business Bureaus—which are an outgrowth of the International Advertising Association, previously known as the Associated Advertising Clubs of the World—have been, and are, carrying on a campaign for truthful advertising that redounds not only to the credit of advertising in general but, in the medical field at least, also operates in the interest of public health.—*J. A. M. A.*, Nov. 9, 1929.

THE USE OF IRRADIATED FOODS

NO subject has so occupied the attention of the medical world in recent years as Steenbock's discovery that exposure of food to ultra-violet rays imparts to it antirachitic properties. Following this discovery, further observations showed that the substance in food responsible for this remarkable effect is ergosterol, which although inert in itself becomes activated when irradiated. Just what change occurs in the ergosterol as a result of this exposure is still unknown.

The antirachitic potency of activated ergosterol (the antirachitic vitamin) is tremendous. Previous to its discovery, cod liver oil was the most concentrated source of the antirachitic vitamin known. Now it has been shown that 1 ounce of activated ergosterol has the same antirachitic effect as 2 to 6 tons of cod liver oil. It is evident that we have at our disposal in irradiated ergosterol a most potent therapeutic agent.

The mode of action of activated ergosterol in the body is not known. It is necessary, however, for the absorption and utilization of calcium and phosphorus from the gastrointestinal tract, for without activated ergosterol the lime salts are not absorbed and deposited in growing bones. In short, activated ergosterol makes substances already present in the food available for the body. There are probably other essential phases of the body metabolism which are dependent on the presence of this substance.

Rickets is a disease chiefly of the first 2 years of life. During this time milk is the most important article of food. The amount of activated ergosterol normally present in milk is so small, particularly during the winter months, that for all practical purposes it should be

regarded as being devoid of this necessary substance, which means that it is essential for every infant and child to receive some substance containing activated ergosterol at least during the winter months. The same holds true for the older child and adult.

It is essential for the physician to have some idea of the amount of activated ergosterol necessary for protection against rickets. From extensive clinical experience it has been found that 3 or 4 teaspoonfuls (about 15 gm.) of good cod liver oil daily is sufficient to protect an infant. The equivalent amount of ergosterol is about 0.2 mg., which is 2,000 times the amount necessary to protect a rat, or 2,000 rat units. It must be understood, however, that the potency of different samples of irradiated ergosterol may vary tremendously, and it is therefore impossible to use the weight of ergosterol as a unit of measurement.

Commercial firms are now beginning to market irradiated food. At present we have little idea as to their antirachitic potency. We may use an irradiated food in the belief that it has enough antirachitic effect to prevent rickets when in reality there is present only one-fifth or one-tenth the required amount. On the other hand we may be giving an overdose with resultant harmful effects. The solution of the difficulty lies in a statement by the manufacturer of the food in question as to the number of units of activated ergosterol present in a given amount. When we realize that 2,000 units is the average daily amount of the substance necessary to protect an infant, we can tell whether the particular irradiated food exerts only a slight antirachitic effect or may be used as the sole source of the vitamin.

The whole question of the use of irradiated foods must be approached with an open mind. It is not impossible that irradiated foods which produce only a slight antirachitic effect in infants, and none in the older child or adult, may still produce other beneficial effects of which we know nothing. The evidence at hand indicates that in irradiated foods we have a most valuable therapeutic agent. However, our practical knowledge of their effect on human beings is still so meager that one hesitates to predict just what place they will play in nutrition.

SHOULD CERTIFIED MILK BE PASTEURIZED?

A STATEMENT in this JOURNAL, July, 1929, page 784, in which certified milk was excepted from the advice urging pasteurization of all market milk, has brought some protests and some inquiries to the Editor.

According to good authority, the most recent statistics show that

Since 1926, malaria has unquestionably been on the increase, for reasons which are not entirely clear. "During 1929, it is said to have become of importance in several areas hitherto considered malaria free."

The State Board of Health of Illinois in commenting upon the conditions in that state a short time ago attributed the increase to the use of the automobile. In the opinion of epidemiologists, medical men and engineers of the Office of Malaria Investigations of the U. S. Public Health Service, there has been no such radical change or increase in automobile travel as to account for the sudden rise in the malaria rate, and in some cases, as between Florida and the North, there has been a distinct decrease since the collapse of the boom in that state. Unquestionably there is greater opportunity for infection among those who camp out along the main routes of travel, and even those in the hotter sections who take evening drives, but there seems no justification for concluding that such travel, which has shown no radical changes in the last three or four years, can be responsible for the sudden increase in the prevalence of malaria.

There are other explanations, none of which seem to account for all of the facts. The spring of 1929 was unusually wet, and some believe that this led to a great increase in the numbers of anopheles. A possible change in the virulence of the malaria parasites has been suggested, while still others hold that unknown factors are responsible for the recrudescence of the disease. Certainly here is a field for careful epidemiological and laboratory work.

That it is possible to reduce the incidence of malaria to the vanishing point even in badly infected areas was shown during the World War in a number of camps in the South. We know the intermediate host and the method of transmission, factors which usually enable us to control a disease. However, the death rate from malaria is comparatively low, and the human factor, which is always the most difficult to deal with, comes into play. The late Dr. Carter, who knew as much about malaria as any man in the world, once said in this connection, that he knew what he could do by draining, ditching, oiling, and brushing, and with such materials as cement and timber, but he did not know what he could do with human beings.

If malaria were a more deadly disease, it can hardly be doubted that our control of it would be easier. On the other hand, it must be recognized that there are still factors which are not well understood, and over which, in consequence, we do not have much power.

DR. FREDERICK MONTIZAMBERT

February 3, 1843 — January 2, 1930

THE long career of a distinguished public servant ended January 2 in the death at Ottawa in his 87th year, of Frederick Montizambert, C.M.G., I.S.O., M.D., F.R.C.S.E., D.C.L.

For upward of half a century (1865-1920) previous to the formation of the Department of Health at Ottawa, the public health work of Canada was carried on almost single-handed by the Director-General. Under his direction the quarantine and Marine Hospital services and laboratories of both coasts and at Grosse Ile in the St. Lawrence were developed. The fine commanding figure of this courtly gentleman, towering head and shoulders above his fellows, has been conspicuous at the public health gatherings of North America since their earliest days. He had been president of both the American and Canadian Public Health Associations, and to his energy and ability much of the public health progress on this continent must be ascribed. Dr. Montizambert was elected to the Presidency of the A. P. H. A. at Charleston, S. C., December 19, 1890, and presided at the Nineteenth Annual Meeting in Kansas City in 1891. He was an Honorary Fellow of the Association.

The younger generation of public health men owe much to the fine public spirit, the wise counsel and the friendship of Dr. Montizambert. He is a notable example of the public servant seen all over the British Empire, whose greatest regard is commonly to be found, at the end of his career, in a sense of duty well done.

Present at the birth of the public work of Canada, Dr. Montizambert witnessed the ravages of typhus, of which he himself was a victim, and of cholera

among the early immigrants. He saw the evolution of the work of preventive medicine, from the mists of empiricism to the scientific atmosphere of the present; he observed the advance of curative medicine and surgery from a similar empiricism to their erection on a scientific basis. But what one best remembers are his kindly qualities, his genial smile, his fervent handgrasp, and his "God bless you, my dear boy!"

LETTERS TO THE EDITOR

TO THE EDITOR:

Relative to a recent editorial in the December, 1929, issue of the JOURNAL entitled "X-Rays and the Public Health," the question is asked, "Will not some progressive health department install a radiologist and invite the practitioners of its constituency to send all their patients suspected of tuberculosis and all contacts of an active open phthisis for X-ray and expert interpretation, whenever the financial status makes it impossible for this aid to be privately obtained?"

I desire to record that the Los Angeles County Health Department has been engaged in just such a campaign since March, 1929. We have a full-time radiologist, who is an expert in chest diagnosis, with two full-time assistant technicians. The latest X-ray equipment is installed at several of our major health centers located in strategic points in the county. Free diagnostic consultations are offered to the medical profession in all cases unable to pay privately for such service, and whenever recommended by the family physician. A campaign among children of high school age was carried out during the months of April, May, and June. A total of 197 selected contact children and those underweight were X-rayed with the following results: 2 cases of pulmonary tuberculosis, adult type, were found, and 11 juvenile cases of tracheo-bronchial glands.

A special summer health school for contact children is maintained each summer, and 78 of these children were radiographed. Of these 78, 48 showed tracheal bronchial tuberculosis. Seven showed the adult type of the disease and 8 showed evidence of both. This work

has proved very popular with the medical profession and we expect to push the campaign vigorously during the coming year. Let it not, therefore, be said that this field of work is overlooked by all health departments in this country.

J. L. POMEROY, M.D.,

Los Angeles County Health Officer.
December 19, 1929

TO THE EDITOR:

In October, 1927, I had the honour and pleasure of saying a few words about the German Hygiene Museum, Dresden, and its activities at the Annual Meeting of the American Public Health Association in Cincinnati, O. Since that time the Museum has constructed a new building for its educational purposes, and this new building will be opened in May, 1930. The exhibits to be shown there will make part of a great International Hygiene and Public Health Exhibition, which undoubtedly will be visited by everyone interested in both these matters present in Europe at the time of the Exhibition.

The idea of the first International Hygiene Exhibition, held in Dresden in 1911, and its initiator, Karl August Lingner, was to open new ways to health education which at that time was rather a new and little explored field. Since then, the Hygiene Museum tries to spread knowledge of the human body and its functions, about sicknesses and the methods of fighting them, about child hygiene and nutrition, etc., all over the world through greater or smaller exhibitions, and through furnishing educational material—almost to the

whole of Europe and even farther. The Exhibition of 1930, including the new displays of the Museum itself, is going to be as important as that of 1911 was, as many Americans, and especially readers of the *American Journal of Public Health*, will remember.

The different parts of it will be:

I. The scientific exhibit of the Museum itself in the new building.

(a) *The Man*—This exhibit has been remoulded totally for 1930. All that will be shown here in 1930—pictures, plastic models, movable models and arrangements to be worked by the public—will be new and quite different from the ancient routine work. Besides the "Transparent Man"—a special way of showing the parts of the human body like tissues under a microscope, of which I could also show some specimens in Cincinnati—another new method will make visible the character of the human body as a scientific and artistic masterpiece of nature.

(b) *Heredity and Eugenics* (Race Hygiene)—These are more modern branches of biology and hygiene, and the group, although shown already in 1911 in its first beginning, is almost totally a new thing.

(c) *Mother and Wife*—This group treats especially of woman's task in reproducing the human race, and of her preparations for this purpose. Her peculiarities as to this special accomplishment are shown, while her position in trade and profession is shown elsewhere in the exhibition.

(d) *Nutrition*—Anatomy of the digestive tract, metabolism, nutritional needs, including the economical problem, vitamins.

(e) *Health and Sickness*—Private and public prevention of disease.

(f) *Health Education*—Pictures, posters, pamphlets, lantern slides, moving pictures, theatre, etc.

(g) *History and Ethnography of Hygiene and Public Health*.

II. The scientific exhibits in the exhibition buildings besides the new Museum building.

(a) *General Care for the Body*—Work and rest, physical culture, care for the skin, the hair, the teeth, bathing, etc.

(b) *Women in Trade and Profession as well as in the Household*—An addition to the above mentioned group, dealing with the biological tasks of woman.

(c) *The Child*—Its development from birth, its feeding and education. Puberty, and its physical and psychical difficulties. Peculiar hygiene of the different age groups.

(d) *Physical Training*—Gymnastics, sports, plays. Anatomy, physiology, hygiene, methods of them.

(e) *Industrial Hygiene*.

(f) *The Human Mind and Mental Hygiene*—Already in 1911 it was realized that in addition to teaching biology of the human body also education about the human mind and its psychology is needed. A connecting link between physical and mental conditions of man is the intention of preventing both of them from becoming sick and therefore less efficient.

(g) *Food and Agriculture*.

(h) *Clothing*.

(i) *Housing*.

(k) *Disinfection*.

(l) *Separate Exhibit*—The Hospital.

III. Exhibits made through the national government, state, provincial, city and county governments; through insurance offices, through private health and hygiene associations, dealing with organization of hygiene and public health work.

IV. Exhibits made through foreign states and the Hygiene Section of the League of Nations.

V. Industrial Exposition.

Please use this letter in any form which seems suitable to you, when you find it might be of some interest for your readers.

Very sincerely,

DR. FELIX TIETZE.

Vienna, Austria

December 8, 1929

TO THE EDITOR:

We have heard overseas postgraduates complain that London is so large, and so complicated, that it takes a few weeks to learn the way around; they also say that, unless they come armed with letters of introduction to physicians or surgeons, it is difficult to obtain the facilities they require. The Fellowship of Medicine was founded to overcome these difficulties, and overseas postgraduates should, as a matter of course, come direct to the Fellowship where, without any charge, they can obtain information, advice and assistance.

We can—and every day do—save time for overseas postgraduates who ap-

ply to us either before leaving their own country or on arrival in England.

Perhaps the main point to be realised is that in England the Medical Year begins in October, and extends through the Winter and Spring until the end of July; August and September being the vacation months, opportunities for work are naturally somewhat curtailed, though the Fellowship endeavours to provide facilities for doctors who are only free for study during that time. We would add, however, that for overseas doctors their arrival in England in August or September means that they will have ample time to settle down and become acquainted with London before starting work in earnest.

We have been told that the information chiefly desired by overseas practitioners is the dates of the various examinations for degrees and diplomas, and the dates, duration and opportunities for securing resident positions in London hospitals, as well as the facilities for Special Courses of instruction. All this information the Fellowship of Medicine is in a position to provide.

As far as the Fellowship itself is con-

cerned, opportunities for clinical work all the year round are provided in the 40 London hospitals with which it is associated, as well as the Special Courses,* and also weekly (free) lectures during the Winter months, and weekly (free) clinical demonstrations (except during August and September). In addition, the Fellowship publishes monthly the *Post Graduate Medical Journal* containing postgraduate lectures, clinical demonstrations, reports of cases, and information on the various courses of instruction. Above all, however, the Fellowship endeavours to help in every way possible medical practitioners requiring advice and assistance, by acting as a central bureau of information, and, of course, no charge is made for this service.

All enquiries should be addressed to the Secretary, Fellowship of Medicine, 1, Wimpole Street, London, W. 1.

Yours faithfully,

H. W. CARSON,

Chairman of Executive Committee
LONDON,
September 12, 1929

* Pamphlets available 1 Wimpole St., London, W. 1.

A. P. H. A. Fifty-Ninth Annual Meeting

Fort Worth, Texas, October 27-31, 1930

Headquarters, Hotel Texas

ASSOCIATION NEWS

STANDING COMMITTEES OF THE ASSOCIATION

THE Executive Board of the Association met in New York on November 16-17 and on December 6. John A. Ferrell, M.D., was designated by the Board as Chairman of the Nominating Committee, and the other members of the committee, one from each Section, were confirmed as follows:

George H. Bigelow, M.D.—Health Officers
Roger G. Perkins, M.D.—Laboratory
George H. Van Buren—Vital Statistics
William H. Dittoe—Public Health Engineering
Henry Field Smyth, M.D.—Industrial Hygiene
James A. Tobey, Dr.P.H.—Food, Drugs and Nutrition
LeRoy A. Wilkes, M.D.—Child Hygiene
Ray H. Everett—Public Health Education
Sophie C. Nelson, R.N.—Public Health Nursing
John J. McShane, M.D.—Epidemiology

With respect to the four standing committees created under the new By-laws, the Chairman of the Board announced that Sally Lucas Jean had agreed to accept the chairmanship of the *Committee on Fellowship and Membership*, and the following additional members of the committee were confirmed:

George C. Ruhland, M.D.—Health Officers
B. L. Arms, M.D.—Laboratory
Louis I. Dublin, Ph.D.—Vital Statistics
E. L. Filby—Public Health Engineering
V. S. Cheney, M.D.—Industrial Hygiene
F. C. Blanck, Ph.D.—Food, Drugs and Nutrition
J. H. Mason Knox, M.D.—Child Hygiene
H. E. Kleinschmidt, M.D.—Public Health Education
Alta E. Dines, R.N.—Public Health Nursing
John A. Ferrell, M.D.—Epidemiology

Similarly, the Chairman announced that Abel Wolman had accepted the ap-

pointment as Chairman of the *Committee on Meetings and Publications*. Additional members are:

Charles F. Wilinsky, M.D.
John E. Monger, M.D.
M. P. Ravenel, M.D.
W. P. Shepard, M.D.

The appointment of members of the *Committee on Administrative Practice* was confirmed by the Board as follows:

C.-E. A. Winslow, Dr.P.H., *Chairman*
Haven Emerson, M.D.
Louis I. Dublin, Ph.D.
George C. Ruhland, M.D.
Henry F. Vaughan, D.P.H.
Allen W. Freeman, M.D.
Charles V. Chapin, M.D.
Sophie C. Nelson, R.N.
George T. Palmer, Dr.P.H.
Michael M. Davis, Ph.D.
W. S. Rankin, M.D.

George D. Lummis, M.D.
W. F. Draper, M.D. } Officers of Health Offi-
E. L. Bishop, M.D. } cers Section
John L. Rice, M.D. }

The organization of the *Committee on Research and Standards* was deferred until the next meeting of the Board.

Meetings of the three standing committees organized have been held. Sub-committees are as follows:

Committee on Fellowship and Membership
Sub-committee on Eligibility
Sub-committee on Membership Promotion
Sub-committee on Affiliated Societies
Sub-committee on Sustaining Membership
Committee on Meetings and Publications
Journal Editorial Sub-committee
Sub-committee on Annual Meeting Program
Sub-committee on Journal Advertising and Annual Meeting Exhibits
Committee on Administrative Practice
Sub-committee on Record Forms
Sub-committee on Rural Health Work

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Conquering Diphtheria—The Philadelphia Department of Public Health in *Healthfax* for November 11, 1929, reports approximately 70,000 children immunized during the recent campaign under the direct supervision of the Department of Public Health. Up to that date there had occurred 828 cases of diphtheria during the year 1929 as compared to 1,731 cases for the same period in 1928, a reduction of 52 per cent in the morbidity total.

In the November 2d *Weekly Bulletin* of the New York City Health Department it is reported that during the first 9 months of 1929 there were 107 deaths of diphtheria and 1,406 cases less than the average for the corresponding period of the previous 6 years. During the first 9 months of the year, 165,000 children were immunized with toxin-antitoxin.

Diphtheria Prevention in Yonkers—E. G. Littell, M.D., Medical Director for the Board of Education at Yonkers, reports upon an interesting and successful endeavor to stimulate the school principals toward securing the immunization of pupils. In Yonkers there is a great deal of rivalry among the school principals and nurses, and it takes but a suggestion to spur them to action. Recently when School No. 20 was first on the list with 96.4 per cent immunized, and School No. 9 was second with 96.2 per cent protected, the principal of the former school remarked that his lead was altogether too slight and he therefore renewed his effort to secure the immunization of the 26 remaining pupils. Two of these received toxin-antitoxin from their own physicians; in 5 instances the principal asked permission

to take the pupils to a clinic in another school. He was therefore able to raise the percentage of immunized children to 97.3, thus putting his school far in the lead. This school is composed chiefly of children of foreign born parentage.

Influenza Incidence—During the epidemic of influenza which swept through the United States during the winter of 1928-1929 an incidence survey was made in the towns of Brewster and Eastham, Mass., located on Cape Cod. A special study was made of the more important epidemiological factors involved in the spread of the disease and also of the outstanding clinical features.

The disease followed the common routes of travel. It was found that personal contact could be held accountable as a means of transmission in approximately 86 to 88 per cent of cases. The total incidence of influenza in Brewster was 33 per cent and 18 in Eastham. The incidence was higher among children, particularly those of school age, than among adults. The family incidence in Brewster was 45.2 per cent; in Eastham 26.9 per cent.

In an effort to determine the source of infection it was found that intimate contact with a clinical case could be established in most instances, and the incubation period was from 2 to 3 days, although the extremes varied from 1 to 10 days. The acute symptoms lasted from 2 to 4 days. Although there were many complications, the most common being pneumonia and otitis media, in the main the disease was uniformly mild and the fatality rate, even in those complicated with pneumonia, low.—S. B. Krámes, *J. Prev. Med.*, 3: 433 (Nov.), 1929.

LABORATORY

C. C. YOUNG, D. P. H.

CONVENIENT PLATINUM NEEDLE

C. S. MUDGE, F. A. P. H. A.

*Associate Professor Dairy Bacteriology, Dairy Industry Division,
University of California, Davis, Calif.*

IT has been the observation of the writer that in many laboratories which he has visited, the platinum needle used was perhaps the one article which had not been improved in the course of time. It was his experience to find usually a glass rod with a wire pushed into the end. Now and then he observed one of the patent arrangements which have jaws to grasp the wire, but these are expensive and soon corrode.

For some time we have used a platinum needle which is cheap and easily made; so it is felt that a description of it might add to the sum total of useful kinks to be used about the laboratory. Figure I is a drawing of the needle as used.

It consists of a glass tube, one end of which may be rounded off in a flame.

Into this glass tube is inserted a copper wire, which is bent in the fingers so as to take a deal of pulling to remove from

FIGURE I

the tube. Into one end of the copper wire a bit of platinum is fused. This fusing is done by holding the two wires in the flame. The copper will soon melt and a little ball of molten copper will form on the end of the wire, into which the platinum—heated to redness—is quickly thrust.

A little practice may be necessary in making the first one, but it will be found to be a very handy needle, much more slightly than the average, and much cheaper than the patented affairs with the jaws which bite into the platinum.

THE COMMINATION OF BLOOD CLOTS FOR CULTURES

T. F. SELLERS, F. A. P. H. A., and JANIE F. MORRIS

State Board of Health, Atlanta, Ga.

THE culturing of blood clots is rapidly becoming a routine procedure in a number of laboratories. Specimens of whole blood are received at the Georgia State Laboratory to be examined by agglutination tests for typhoid, Brill's (typhus), undulant fever and tularemia, also for syphilis by the Wassermann and Kahn tests. Ninety-

five per cent of all such specimens are submitted in Keidel vacuum tubes.

After the serum is drawn off for the serological tests the clot is placed into bile glycerine, broth or brain liver infusion (Hibler's), depending on the purpose of the culture. Where only a typhoid or paratyphoid culture is requested, the clot goes into bile glycerine

medium and is dissolved. If any general or specific culture other than typhoid or paratyphoid is requested, the clot is placed in plain or glucose broth or Hibler's which does not dissolve it. It would, therefore, be possible for organisms to be trapped in the mass so as not to escape. Such cultures may be negative even after several days' growth. To avoid this possibility it was necessary to devise a method of breaking up or comminuting the clot. Two methods have been devised.

Because of the tough slippery nature of the clot, such instruments as stiff platinum needles, glass rods, scalpels and forceps proved unsatisfactory. It was found that the ordinary three pronged long handle pickle or oyster fork with the tips of the prongs ground down to a cutting edge about $\frac{1}{8}$ inch in width answered the purpose fairly well. After the clot has been dropped into the medium the sterile fork is used to chop it into small particles.

While the pickle fork method was a great improvement over any device previously tried, its use at best requires several minutes during which time the mouth of the culture bottle or flask is exposed to contamination; so we tried forcing the clot through the nozzle of a Luer syringe. This works excellently. An ordinary 10 c.c. Luer syringe is sterilized, preferably by dry heat. After sufficient serum has been withdrawn for study, the remainder of the specimen, including the clot, is dropped into the barrel of the syringe, the plunger inserted for a short distance, and the barrel turned with the nozzle upward, to expel the air with the plunger. The nozzle is then held over the mouth of the medium container and the clot "spued" into the media by pressure on the plunger. A thorough comminution of the clot is thus obtained. In our experience this is less apt to be attended with extraneous contamination than the pickle fork method.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Health in Iceland—In many respects, public health problems in Iceland are unique. There are many striking differences in the behavior of certain diseases in Iceland and in other countries. The country's remarkable immunity to certain diseases which are relatively common elsewhere is, to a large extent, an unsolved problem. Acute rheumatism is very mild and resultant cardiac complications are infrequent. Lobar pneumonia is frequent, 19 per cent of the cases occurring in patients under 15 years of age. Diabetes is almost unknown and cancer of the uterus is very rare. Cerebral apoplexy is common in the almost complete absence of

syphilis and it has been observed that cerebral apoplexy runs in families.

There are about 100 doctors in Iceland, 48 of whom act as medical officers of health. Few figures are so demonstrative of the progress made during the last decades as those dealing with vital statistics. The average infant mortality of 52.3 per 1,000 births in the 5-year period 1921-1925 is among the lowest, if not the lowest, in Europe. Until the last quarter of the 19th century, tuberculosis was hardly known in Iceland. In 1921, the number of notified cases was 745, and in 1927, the number increased to 1,100. The tuberculosis death rate for the period 1911-1915,

with an annual average of 147 deaths, was 1.7 per 1,000 population and in the period 1921-1925, with an annual average of 186 deaths, the rate was 1.9 per 1,000 population. The first tuberculosis sanatorium was built in 1910. Leprosy was formerly rife in Iceland but in 1927 the number of lepers was reduced to 44. Gonorrhea became endemic in 1890 and syphilis after 1900. The influenza epidemic of 1918 reached Iceland and lasted for 5 months. Three districts escaped completely by voluntary isolation. A serious outbreak of epidemic pleurisy occurred in 1926. An epidemic of measles was imported in 1924 and lasted until 1926. Prevention by injection of the serum of convalescents was found effective in some districts.

Hydatid disease of the liver was so common 60 or 70 years ago that 2 per cent of the inhabitants were supposed to suffer from it. Drastic measures have been taken against it and it is now becoming rare. Enteric fever has long been endemic in Iceland, with serious outbreaks from time to time. Scarlet fever became endemic early in the present century but only 5 cases were reported in 1927. Acute poliomyelitis had been rare until 1924 when a serious epidemic broke out suddenly. An epidemic of whooping cough was imported in 1926. The rarity of rickets is in dispute but it is far from being as common in Iceland as in the Faröe Islands.—Observations in Iceland, *Lancet*, 2: 745-750 (Oct. 5), 1929; *Lancet*, 2: 801-802 (Oct. 12), 1929.

The League Steps Out for Greece
—The League of Nations was requested to make a study of sickness and its prevention in Greece and present a plan for national health administration. The Health Committee accepted the obligation and a survey was begun. The group of health surveyors found a population almost exactly that of New York

City; no machinery for disease control except port quarantine; about 30 trained nurses; death rates of about 14 to 22 per 1,000 and birth rates about 18 to 30 against a death rate averaging 12.3 and a birth rate 19.7 in the registration area of United States. They found 23 per cent of deaths so indiscriminantly reported as to be unclassifiable.

Typhoid rates in Greece are about 40 to 53 per 100,000, due to water soiled by surface drainage. About 20 per cent of deaths are from diarrhea and enteritis in children under 2 years, and about an equal number from tuberculosis, with malaria a close third. There is no compulsory notification of acute communicable diseases of childhood or of tuberculosis or venereal disease. The prevalence of scarlet fever and diphtheria is very low. Tuberculosis was not serious until the housing and economic crises of the past decade; the rate in Athens in recent years has reached 400 per 100,000 population and now is 300 or over. Similar tuberculosis rates prevail in Patras and Corfu and rates as high as 544 are reported from the smaller Cyclades. In rural regions where grazing and grain growing conditions are good, rates of 150 or under are found. Malaria is prevalent in Peloponnesus and Macedonia, from 30 to 90 per cent of children being found with malarial infection by means of the spleen index. Trachoma is a steadily increasing scourge and is prevalent in from 5 to 10 per cent of all school children. Athens disclosed 75 to 100 active cases of leprosy under no administrative supervision and without medical control. Only a few hundred of the probable 1,000 lepers in Greece are exiled. As would be expected, rabies is rampant.

The maternal mortality of Greece is low, apparently because of the small amount of interference with delivery and the vigorous physical condition of peasant women. Owing to the prevalence of breast feeding, infant mortality

in Greece is not high. Although it reaches 140 in some cities, it is more commonly 90 per 1,000 live births and is found as low as 60.

After 6 months of training in England and various European cities and rural areas, a picked group of young Greek physicians will, in February, form as members of the School of Hygiene and Health Center in Athens the nucleus of a permanent Hellenic Health Service. For 5 years the League will provide a professor of preventive medicine and director of the school, a chief of a division of malariology, and a sanitary engineer. The organization will be that of centers serving health districts according to local needs and subject to technical direction and advice from the Athens center and School of Hygiene.—H. Emerson, *Survey*, 63: 283-286, 308-309 (Dec. 1), 1929.

Sickness in Essex County—An intensive morbidity study was carried out in Essex County from October, 1927, to September, 1928, to supplement the Rural Survey conducted by the New York State Department of Health in 1927. The estimated population of Essex County is over 18,000, the number of persons for every physician averaging about 900. The cases of sickness totalled 19,179. Communicable diseases numbered 312, or 1.6 per cent of the total cases. The number of cases of sickness reported among women was slightly higher than among men. Surgical cases numbered 2,641 among men and only 1,312 among women. The leading cause of non-reportable diseases was cold with a total of over 5,000 cases, or 26.8 per cent of all non-reportable diseases. Surgical cases (except gynecological) were responsible for 21.0 per cent, followed by cases of digestive disorders with 12.2 per cent, that is, 60 per cent of all causes of sickness were listed under these three heads. Of the 1,055 cases of nervous disorders, one-

seventh were given as organic and the rest functional. Cases of diseases of the skin totalled 851, one-third of them being contagious. Of the total 535 cases of diseases of the heart, 121 were rheumatic, 9 syphilitic and 405 classified as "other forms." There were 30 cases of syphilis reported, 2 being congenital and the rest acquired.

Surgical cases represented 28.3 per cent of all cases among males and 13.8 per cent among females. Cases of digestive disorders were more prevalent among women, 13.6 per cent, as compared with 10.8 per cent among men; and the proportion of cases of nervous disorders was more than double the corresponding figure for men, 8.0 per cent and 3.1 per cent respectively. Among women, one-tenth of the total of sickness was headed gynecological. Operative treatment was needed in 130 of the 1,001 cases reported. The number of cases of gonorrhea among men, 165, was 6 times that among women, 28, corresponding percentages being 1.8 and 0.3.

The leading reportable disease was scarlet fever with 35.6 per cent of all cases, followed by mumps, 18.3 per cent, and pneumonia, 14.4 per cent. Gonorrhea is the most prevalent communicable disease in the section of the county represented in the survey, the total number of cases exceeding by more than 70 per cent that reported for scarlet fever. Syphilis was sixth, taking precedence over tuberculosis. The greatest amount of sickness, 26.7 per cent, occurred during the three winter months and the least, 23.3 per cent, during the third quarter of the year.

Comparing the Essex County Survey and the Rural Survey, it was found that in general the points of similarity were much more numerous than the points of difference. Communicable diseases represented a higher percentage, 3.3, in the Rural Survey than in the Essex County Survey, 1.6 per cent. The proportions of colds in the two surveys were practi-

cally the same. This survey was valuable in that it gave support to the important facts brought out in the more extensive Rural Survey.—J. V. Deporte, *New York State J. Med.*, 29: 1310-1316 (Nov. 1), 1929.

A Smallpox Outbreak in Massachusetts—This is a report of an outbreak of mild smallpox in one Massachusetts community with a population of about 10,000 over a period of 4 months. There were 223 cases reported and no deaths occurred. The 223 cases occurred in 113 families totalling 620 individuals. After 65 cases had been reported as chicken pox, an investigation was made and all of the cases were pronounced smallpox. From 1924 to 1928 about 86 per cent of the cases of chicken pox that occurred were in the 0-9 year age group, whereas in this outbreak of smallpox but 19 per cent of the cases occurred in the same age group. Most of the cases were very mild and of the discreet type. About 9,600 individuals were vaccinated within 3 days of the analysis of the disease. Only 2 of the 223 cases had been successfully vaccinated and these more than 30 years ago. Of 23 contact cases that developed outside the community, 22 were in nearby Massachusetts towns and 1 in New York City. Of these, only 4 had been previously vaccinated, and these more than 20 years ago. Forty-one cases were distinctly modified by vaccination. Nineteen of these 41 cases had their onset within 3 days after vaccination. Seven of the 23 contact cases were modified by vaccination. Up to July 1, 1929, Massachusetts had reported 272 cases of smallpox, 223 being directly concerned with this outbreak and 23 of them contact cases. Massachusetts has not had as many as 272 cases of smallpox reported in any previous year in the past 26. This particular community had evaded the compulsory public school vaccination law

for a number of years.—P. McKnight and L. Scamman, *New England J. Med.*, 201: 361-362 (Aug. 22), 1929.

Diabetes Record for 1928—A study of preliminary census returns from 21 states and Hawaii showed that the number of diabetes deaths had increased from 6,093 in 1927 to 6,808 in 1928. Nineteen states showed increases in the death rates, while only two, Delaware and New Hampshire, showed declines. In spite of a decrease of 2.4 per 100,000, New Hampshire reported a rate of 27.9, the highest rate for the 22 localities. Vermont had a rate of 27.0 and Arizona, 5.9, the lowest reported. A further study of 50 cities since 1912 showed an increase in the diabetes death rate from 15.9 to 23.2 per 100,000 in 1928. The rates for last year were the highest on record. Another study of the diabetes death rates for 1927 and 1928 for 141 cities of the United States based for the last year on a population of nearly 38,000,000 showed that diabetes death rates had increased in 94 cities and declined in 47 others. The rate for the 141 cities increased from 19.4 per 100,000 in 1927 to 22.1 in 1928. Of the 141 cities, Yonkers had the highest rate for 1928, 44.5, closely followed by Schenectady, 42.9, and Utica, 40.3 per 100,000. The 6 largest cities in the United States, all with a population of a million or more, showed increases from 0.6 per 100,000 in Detroit to as much as 5.6 in Cleveland. The New York City rate showed an increase of 3.1 and the rate for Philadelphia increased 4.9 per 100,000. A detailed study revealed no particular concentration of diabetes deaths in any section of the country. Some very curious contrasts resulted. The rate for Minneapolis was 24.1 per 100,000 while that for St. Paul was 13.4. The rate for San Diego was 35.9 as against only 14.9 for Los Angeles. A study of frequency rates and the per capita sugar consumption for 8 countries

confirmed the viewpoint that an excessive sugar consumption is one of the direct contributory causes toward an excessive death rate from diabetes. Italy with a diabetes death rate of 5.5 per 100,000 and a sugar consumption per capita of 8.1 kilograms showed quite a contrast to the United States with a rate of 17.3 and a per capita sugar consumption of 48.1 kilograms.

Diabetes is less common among negroes than whites. In 1926, the adjusted diabetes death rate for the registration area of 1920 was 18.1 per 100,000 for the white population and 12.7 for the colored. In a typical state, as South Carolina, the rate for the white population was 10 per 100,000 while the negro rate was 8.1. In Tennessee the negro rate, 9.2, exceeded the white rate of 8.6. The death rates for females are higher than those for males. In 1926, the adjusted male diabetes death rate was 14.1 against a rate of 20.9 for females.—F. L. Hoffman, *Spectator*, 123: 19–21 (Nov. 7), 1929.

Vital Statistics for Northern Ireland—The Registrar-General of Northern Ireland has just published the annual report for 1928. This report is the first for Northern Ireland to contain death rates standardized for age and sex distribution of the population. These rates are the ones that would be experienced if the mortality rates of the

community at various ages and sexes were to prevail in a population selected as standard. The standard population adopted is that of England and Wales in 1901, and as this is also used as a standard for England and Wales, the rates for the two countries are comparable. The standardized rate for Northern Ireland in 1928 is 11.6 per 1,000 population, which compares with a rate of 9.9 per 1,000 for England and Wales. A notable feature of the comparison of the standardized rates is the relatively high rates for females in Northern Ireland, these rates being on the average in the years 1926–1928 about 96 per cent of the rates for males whereas the corresponding ratio for the England and Wales rates is only about 81 per cent. In general, the more rural areas of Northern Ireland enjoy the lowest death rates.

The report also includes annual abstracts giving in detail the number of marriages, births and deaths during the year. The birth rate for 1928 was 20.8 per 1,000 of the estimated population, or 0.5 below that for 1927. There are included numerous comparative tables and notes relating to infant and maternal mortality, inquests and causes of death. Of all single defined diseases, heart disease bears the greatest proportion to the total deaths at all ages, which is the usual experience.—*Annual Report for Northern Ireland for 1928*.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

STREAM POLLUTION CONTROL IN ILLINOIS

H. F. FERGUSON

*Technical Secretary, Sanitary Water Board; Chief Sanitary Engineer,
State Department of Public Health,
Springfield, Ill.*

UNTIL July 1, 1929, three separate state departments had some jurisdiction relative to stream pollution prevention and abatement, and a fourth department made studies and investigations of pollution but had no authority to take corrective action. This divided and overlapping authority did not make for efficiency or economy in field investigations nor promote effective action. Further, it resulted in separated records dealing with the pollution and the quality of the waters in Illinois. Also, none of the laws under which the departments operated up to July 1, 1929, were very definite or fully effective for handling sewerage and stream pollution work.

The Illinois government under the governor is divided into 11 departments, with a director of each department appointed by the governor. The departments in turn are divided into divisions. The stream pollution law that became effective July 1, 1929, established the Sanitary Water Board composed of the directors of the 4 departments that have interest in some phase of stream pollution, sanitation, and conservation, and a fifth member appointed by the governor to represent manufacturing interests: The 4 departments are Public Health, Conservation, Agriculture, and Purchases and Construction (Division of Waterways). The chief sanitary

engineer of the State Department of Public Health is designated as ex officio technical secretary of the board.

The law makes it the duty of the Sanitary Water Board to study, investigate and determine ways and means of eliminating pollution from the streams and waters of the state, and of preventing such pollution that is detrimental to public health or to the health of animals, fish, or aquatic life, or detrimental to the practical use of the waters for recreational purposes.

Pollution is defined by this act as existing in any of the said waters if,

... as the result of any discharge of any liquid or solid substance, the quality of any of said waters, after reasonable treatment, is impaired for public water supply, bathing or recreational purposes, if said waters were reasonably capable for use for public water supply, bathing or recreational purposes before the discharge occurred of which complaint has been made to said Sanitary Water Board; or, if obnoxious odors result from such discharge into any of said waters near buildings, roads and lands occupied or used by human beings, *provided* that odors shall not be deemed to be obnoxious in any case where the Sanitary Water Board has determined that the discharge causing such odors does not constitute pollution within the meaning of this Act; or, if the quality of any of said waters is impaired for the use of live stock, or kills, or is injurious to fish life, when said waters were reasonably practicable for use for watering live stock or for fish life.

The Sanitary Water Board shall have the

Additional work has included special analyses of river samples at critical points, analysis and measurement of certain industrial wastes and sewage, inspection of industrial plants, and other field investigations properly coming within the scope of the activity.

The working personnel has been as follows:

North Central District—One sanitary engineer, employed by the committee on full-time basis, a faculty member of the chemistry department half-time during summer months, one graduate student and one undergraduate student during the four summer months.

Southwest District—First assistant engineer of the State Department of Health (about one-third of his time), a member of a faculty half-time for four months, one graduate student full-time for four months, and a student full-time for two months. In addition, three other members of a faculty have given assistance.

Necessarily, the general supervision and planning of the surveys has required a considerable portion of the time of the chief engineer of the State Department of Health.

The biological studies are being made by a graduate of the University of Virginia, in connection with his work for a doctor's degree.

Mention should be made of the survey of the James River by the City of Richmond during the fall of 1928. This was undertaken in order to determine the causes of certain difficulties at the water filtration plant. The conclusion was reached that wastes from a large paper plant, 245 miles upstream, seriously interfered with the chemical treatment of the supply during low river stages and that certain other trade wastes were partly responsible in a lesser degree. A well known firm of consulting engineers was employed. The cost of the survey was about \$10,000. A report has not been published.

STREAM POLLUTION IN WEST VIRGINIA

L. KERMIT HERNDON

*Chemical Engineer, State Water Commission,
Charleston, W. Va.*

WEST Virginia has had anti-stream pollution laws in the past similar to those in other states. The Game and Fish Commission was interested in so far as the pollution affected fish life and did some very good work in reclaiming some streams. The law was difficult to administer as it strictly prohibited dumping of material injurious to fish life into the streams. The suits brought by sportsmen and others were not effective in eliminating the condition, but rather stirred up ill feeling between the industrial and recreational groups. The situation called for a program of scientific study and re-

search rather than the imposition of fines.

The Health Department was interested in stream pollution in so far as the pollution affected the public water supplies. The supervision of sewage disposal also directly connects this department to any program of stream reclamation.

Each year the problem of stream pollution came up for discussion at the short school, held jointly by the Sanitary Engineering Division of the State Health Department and the College of Engineering at the State University, for the instruction of filtration plant oper-

ators and water works superintendents. They recommended that the Legislature provide funds for research on stream pollution.

The coöperative effort of the state sanitary engineers on the Ohio River watershed and industry in removing the phenol wastes from the streams gave impetus to the movement for stream pollution control.

An attempt was made to secure the coöperative support of a group composed of representatives from the State Health Department, State University, Manufacturers Association, Coal Operators Association, Fish and Game Commission, Wild Life League, and the Conference on Water Purification, to a research program financed by the Legislature and carried on at the University of West Virginia.

The industrial group felt the need for a definite program or policy regarding stream pollution and realized the inadequacy of the law at that time, and other groups, such as the recreational and public health, wanted more effective legislation too. Hence, a committee made up of representatives from each faction met and drew up a bill for presentation to the Legislature. This bill creating the State Water Commission was passed by the legislature, signed by the Governor and became effective June 1, 1929.

The State Water Commission is composed of the Commissioner of Health, the Chairman of the Public Service Commission, and the Chairman of the Game and Fish Commission. The Director of the Division of Sanitary Engineering in the State Health Department is required to perform such services as may be requested by the Commission in connection with its duties. The College of Engineering at West Virginia University is requested by the law to render such assistance, in so far as it can, in the study of ques-

tions connected with pollution of waters. The Commission has elected the Commissioner of Health as its Chairman and has selected the Director of the Division of Sanitary Engineering as its Secretary. Executive authority is vested in the Commission.

The law authorizes the Commission to investigate, hold hearings, and enter orders regulating specific cases of pollution. It may specify the system to be used, or correct and approve the plans submitted. The cost of the installation, maintenance, and operation of the system must not be unreasonable or inequitable. The Commission may cause the enforcement of any of its orders in the courts. Any person aggrieved by an order of the Commission has recourse to the courts.

At present the funds for the operation of the State Water Commission come from the three commissions represented on it, each bearing an equal share. These funds are limited. The Legislature in passing the bill did not provide funds for its operation. A provision was made in the act whereby the Commission could coöperate with any public or private experimental agency and receive therefrom, on behalf of the state, and for deposit in its treasury, any money such agency might contribute as its part of the expense. The personnel now consists only of a chemical engineer working under the direction of the Commission and doing both the field and laboratory work.

During the past summer a study was made of the Cheat River Basin in which the various sources of pollution were located and classified. The quantity and quality of the wastes were determined as well as their effects upon the stream. Studies were made upon the self purification of the stream and its recovery from the pollution load. A detailed study was made of the lake formed by a large water power dam lo-

cated at Cheat Haven. This report has been printed for distribution. The work was carried on jointly by the State University represented by the Professor of Sanitary Engineering, and by the State Water Commission represented by its chemical engineer. The report was written jointly. Since the wastes from mines constitute a serious problem in this state, the State University is planning a research program upon this subject. An advisory board has been formed of prominent mine operators and engineers to assist in the work.

A reconnaissance survey was made of the tanning industry within the state

and an agreement has been formed whereby a more efficient and satisfactory disposal of tannery wastes will be instituted.

The Commission has also become interested in sewage disposal and has informally requested action in two critical conditions where public water supplies are affected.

Future work includes a study of the public water supplies of the state and detailed work on tannery and other industrial wastes. A detailed pollution survey and study will be made of another watershed with the coöperation of a municipal water board engineer located on the shed.

Solving Oil Field Waste Disposal Problems—The Santa Fe Springs Waste Water Disposal Company, a non-profit coöperative organization, was formed by 20 oil producing companies to dispose of the salt water brought to the surface in oil well operation at Santa Fe Springs, Calif. The waste water is passed through settling and skimming tanks to remove mud and oil, raffle ramp aerators being provided to release oil in suspension. These tanks reduce the oil from an initial content of 400 or 500 p.p.m. to about 12 p.p.m., resulting in a daily oil recovery ranging from 200 to 400 bbl. A vitrified clay pipe line varying from 18 to 24 inches in diameter carries the effluent waste water 81,000 feet to the ocean.—Anon., *Eng. News-Rec.*, 102, 20: 795-798 (May 16), 1929. Abstr. D. E. Kepner.

Movement of Water in Alluvium.
—To determine the possibility of procuring a certain amount of underground

water in the Loire Valley (France), the studies described here were made. The underground water in this valley comes partly from the bed of a river and a canal by percolation, and partly from drainage from the hills. The point of contact between the hill and the river waters has a to-and-fro movement. As a means of finding the proportions of each type of water, chemical analysis was used as the hill water has a larger chalk content. Temperature was employed also, as the conduction of heat to deep levels in the earth is known to be small.

To find the direction of flow in the ground, iron tubes having perforations were sunk at the angles of a pentagon. In the center other similar tubes into which colored solutions were poured were sunk. The strength of the solution as it appeared in the outer tubes gave information concerning the flow.—F. Dienert, *Ann. d'hyg.*, V: 6, 669-691, 1928; *Bull. Hyg.*, 4, 4: 324 (Apr.), 1929.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

The Evaluation of 5 and 7 Per Cent Carbon Dioxide Mixtures as Respiratory Stimulants—Summary—

1. Healthy young adults at rest experience very varied degrees of response when given inhalations of 5 and 7 per cent carbon dioxide in air. 2. In some subjects the response to 5 per cent carbon dioxide consists in little more than a doubling of the normal minute-volume. 3. Seven per cent carbon dioxide induces the maximal ventilation obtainable without causing undue discomfort to normal subjects. 4. The same subject breathing identical concentrations of carbon dioxide responds differently on different days but does not lose his characteristic type of response.—Emery Haller, Walter Killiches, and Cecil K. Drinker, *J. Indust. Hyg.*, XI, 9: 293-313 (Nov.), 1929.

The Use of 7 Per Cent Carbon Dioxide and 93 Per Cent Oxygen in the Treatment of Carbon Monoxide Poisoning—From the conclusions: A study of the experience since 1923 in the use and experimental examination of the effects of 5 per cent carbon dioxide and 95 per cent oxygen in the treatment of carbon monoxide poisoning has indicated the wisdom of increasing the concentration of carbon dioxide to 7 per cent for the first 5 to 20 minutes of treatment. No experimental or clinical evidence has appeared indicating that the increase in carbon dioxide to 7 per cent carried with it the slightest danger. Indeed, all facts point to benefit to the circulation from 7 per cent carbon dioxide in 93 per cent oxygen. Three hundred cases have been so treated, and the treatment completed

with the usual 5 per cent mixture. The results of this field work have been uniformly good.—Cecil K. Drinker and Thomas J. Shaughnessy, *J. Indust. Hyg.*, XI, 9: 301-313 (Nov.), 1929.

Some Physiologic Reactions to Cooling Power during Work, with Special Reference to Evaporation of Water—From the summary: The cooling effect of wind caused a decrease in pulse rate, but this was observed less in lightly clothed subjects than in those nearly naked. Also, the increase was greatest under the warmest conditions studied, i.e., in the lightly clothed subjects working in moist air.

Rectal temperatures as a rule, but not always, increased slightly, by 0.5 to 1° F., during work at 25° C. Again, the heat produced during work was three times that produced while at rest. There are likewise variations in the response of different subjects with regard to water evaporation—from nil for the coldest conditions to 240 gm. per hour under the warmest conditions.

“Greater use should be made of removal of clothing and movements of air to render conditions comfortable for indoor muscular workers. If this is done, there is a wide range of atmospheric conditions above and below 15° C., under which comfort is attained with moderate work.”—J. Argyll Campbell and T. C. Angus, *J. Indust. Hyg.*, XI, 9: 315-327 (Nov.), 1929.

Physical Examination of Athletes—A movement concerning chiefly working classes has resulted in the physical examination thus far of more than 3,000 young men and women, ranging in age

between 15 and 24, and the results are a great surprise, for more than 50 per cent of the persons who engaged in sport activities presented defects of such a nature as to make such participation inadvisable. Especial attention was given in the examination to the heart, lungs, gastrointestinal tract, and a functional testing of the organs of circulation and respiration, of the eyes and ears, and a urinalysis.

The most frequent obstacles to participation in sports lay in disorders of the lungs and the heart, the existence of which the patient was not infrequently unaware. Anomalies of the spine, disease of the tonsils, and flatfoot and sagfoot were very frequent, the last two in workmen.

In women, hysteria was a frequent condition and to these mountain climbing and swimming were usually forbidden. Nevertheless interest in sports has resulted in a marked decrease in smoking and drinking in all classes.

The sport committees have decreed that only such athletes may participate in contests as have submitted to a careful examination. "It is an interesting fact that especially football players and those who engage in heavy athletics endeavor to avoid the examination, if they are 'professionals,' because they fear the results."—*Vienna Letter, J. A. M. A.*, 93, 22: 1747-1748 (Nov. 30), 1929.

United Fruit Company, Medical Department, 17th Annual Report—

This volume of some 400 pages with many full-page illustrations in half-tones, charts, diagrams, etc., devotes: Sec. I, to comments on some of the more important diseases occurring in the tropical divisions of the company's interests; Sec. II, to a number of papers upon malaria; Sec. III, to dysentery, and other tropical diseases both of the employed and their families; Sec. IV, to surgical disabilities; Sec. V, to diseases of the special senses, pathology,

food poisoning, snake bite cases, etc.; and Sec. VI, to organization and vital statistics.

While malaria causes a greater amount of sickness than any other single infection on the plantations of the company, lobar pneumonia causes the greater number of deaths. The incidence of pneumonia does not differ materially from year to year while the fatality is high—28 to 37.5 per cent. Contributing factors are the lowered resistance of the native Indian, Negro and mixed races; the high labor turnover, which decreases the income; the malnutrition, malaria, hookworm, syphilis, etc., which exist; also the prevalence of influenza. The 1928 epidemic was mild in form and occurred in all the Central American, Columbian, and West Indian plantations except Cuba.

There were only 35 cases of typhoid fever among the employees in all of the divisions (apparently involving 55,604 total employees), the chief sources of infection being traced to carriers and to flies. During the year nearly 8,000 injections of typhoid vaccine were used. Amebic dysentery has decreased from 536 cases with 17 deaths in 1926 to 331 cases with 3 deaths in 1928. The bismuth-subnitrate method of treatment has proved simple and effective and few cases resist treatment, while relapses are rare. Beriberi is increasing in some of the divisions, there being a total of 42 cases reported in 1928. The degree of hookworm infestation in the localities where the company operates is generally low, and oil of chenopodium is the vermifuge of choice. This disease is not one which appears to play an important rôle in the prevailing anemia.

Not a single case of either smallpox or alastrim was encountered in any of the plantations during the year. Diphtheria in the tropics is rare and usually of mild character. Of 228 cases of pulmonary tuberculosis treated in the hospitals, 150 developed among the labor-

ing population while there was a total of 36 deaths. Erysipelas is treated by the application of pure carbolic acid until the surface turns white when pure alcohol is applied. The results have been exceedingly gratifying, the temperature falling within 3 to 6 hours, and no further treatment is necessary. Herpes zoster is treated by the same method, and usually within 24 hours the patient can return to duty. Likewise, 5 per cent methylene-blue in water seems effective in erysipelas. Venereal diseases are a serious menace and of growing importance. Laws are rarely enforced, so that the social leper is generally permitted to run rampant, and many cases have to be hospitalized.

(The interested reader should consult this very replete volume for further information covering the diseases of tropical workers who are under elaborate medical supervision.)—United Fruit Company, Medical Dept., General Offices, Boston, Mass.

Sickness among Industrial Employees during the First Three Months of 1929—During the past 9 years a group of approximately 35 sick-benefit associations in industry has reported to the U. S. Public Health Service the cases of illness and nonindustrial accidents causing disability for 8 consecutive calendar days or longer among its members, and the monthly number of male and female members. The results have been published annually, but the present report is an attempt to supply a current index of illness of the adult occupied population covered.

An increase of 38 per cent, compared with the first quarter of 1928, is shown in the incidence rate of disabilities lasting more than 1 week. The respiratory diseases showed an increase of 86 per cent—due to the influenza epidemic, which disease was 163 per cent more frequent than in the same period the year before. Likewise, the pneumonia

rate was 28 per cent higher. Deaths followed the increased frequency of sickness. A large insurance company reported an increase of 18 per cent in the industrial death rate for the quarter. In fact, the death rate for the quarter appears to have been higher than during the first 3 months of any year since 1920. Sickness from diseases other than respiratory had about the same frequency as in the previous year.—U. S. P. H. S., *Health News Release*, Jan. 1, 1930. See also *Reprint No. 1316* (Sept. 13), 1929.

Efficiencies of Painters' Respirators Filtering Lead Paint, Benzol and Vitreous Enamel Sprays—This determination of the efficiencies of respirators was made through a coöperative arrangement between the U. S. Bureau of Mines, the National Safety Council, and the U. S. Public Health Service. The specific questions which it was proposed to answer were as follows:

1. What filtering material, if any, is adequate—
 - (a) To reduce the lead content of the air to which a spray coater is exposed from 200 mg. per cu. m. to 0.6 mg. per cu. m.?
 - (b) To reduce the amount of benzol under similar conditions from 2,000 to 75 p.p.m.?
 - (c) To reduce the number of silica particles under similar conditions from 200,000,000 to 100,000 per cu. m. as determined by the Palmer method?
2. How long would a layer of such material function?
3. How do certain typical masks now available measure up to this standard?

In general, respirators with cotton, paper, or fabric filters remove 90 or more per cent of the lead from air carrying paint mist, and restrain none of the solvent vapors. The addition of a canister or cartridge of activated charcoal to the respirator removes all solvent vapors until the charcoal becomes saturated. Usually, fresh filters are necessary at intervals of several hours, while

fresh cartridges of charcoal must be used when the latter is saturated, but canisters may last for weeks before a change is necessary. Respirators were somewhat less efficient against the silica-dust sprays, although most of those submitted for tests were more than 50 per cent efficient.—S. H. Katz, E. G. Meiter, and F. H. Gibson (U. S. Bur. of Mines), *Pub. Health Bull.* 177, 27 pp. ill., June, 1928.

Regulations for Spray-Coating—These regulations set forth the rules to safeguard the lives, limbs, and health of workers in spray coating operations, and place the responsibility of compliance upon both the employer and employee, with provisions for penalty, also for petition for modification.

The pamphlet discusses administration, definitions, specifications—their application, the specifications for booths—exhaust systems, rules of cleaning booths and spraying equipment, containers for spray materials, electrical equipment, additional requirements for protection against fire, exceptions for use of noncombustible materials, and additional requirements for health and sanitation. A final section covers features for health protection and protection from fire, arranged as recommendations. Ten plates for setting up equipments are included.

Among particularly interesting features are the definitions, the handling of vitreous enamel and siliceous materials, the rate of air velocity in booths, and the 17 special recommendations for health protection.—Penn. Dept. of Labor and Industry (*Special Bulletin*), 35 pp., 1929 ed.

Industry Reports, Published to Assist Underwriters in Classifying Industrial Hazards—The following list of articles has been published during the course of the year 1929, and an Index to all Volumes, I to IV, inclusive,

has likewise been published. Each report consists of from 6 to 16 pages depending upon the nature of the industry or hazard discussed, and contains certain illustrations, tables, and an index to occupations (whenever a given hazard is discussed). Vol. IV, 1929:

- No. 1—Household Electric Refrigeration
- Nos. 2-3—Coke and By-products
- No. 4—Gypsum Industry
- No. 5—Turpentine
- No. 6—Tobacco Products
- No. 7—Chromium Plating
- No. 8—Industrial Alcohol
- No. 9—Lumber Industry
- No. 10—Physical Impairment in Clerical Occupations
- No. 11—Methanol (wood alcohol)
- No. 12—Artificial Leather
- Retail Credit Company, Atlanta, Ga.

Health Hazards in Industry—J. J. Bloomfield, Asst. Physical Chemist, U. S. Public Health Service, with 15 pages of discussion at the 15th Annual Meeting of the International Association of Industrial Accident Boards and Commissions. U. S. Bureau of Labor Statistics, *Bull. No. 485*, 130-156 (June), 1929.

The Pathology of Silicosis of the Lung—In Ontario, silicosis has been found to affect chiefly gold miners, granite cutters, and metal grinders, but occasionally cement workers and quarrymen are affected. Clinically the study of this disease has practically reached a standstill, but pathologically it presents many aspects which invite investigation.

The lungs of 12 autopsy cases were carefully studied and the silicotic lesions divided into 5 different stages (which are described). The known periods of exposure ranged from 4 to 27 years. The diagnosis had been: 6 of tuberculosis, 2 of nephritis (including 1 with lobar pneumonia), 1 pneumonia, 1 heart disease, 1 external violence, and 1 unknown (mitral stenosis). The known

silica content of ash of the lung (shown in a table) varied from 6.24 to 45.32 per cent. Doubly refracting particles seen under the high power in 4 or more selected fields ranged from 3 to 96, while exogenous pigment of clay, iron, and carbon nature was present in all.

There was found to be no parallel between the amount of visible crystals and the per cent of SiO_2 in the ash, and the term "occult" is used to designate that portion of the silica which is invisible. "Occult" silica varies directly as the amount of fibrosis present.

Gye and Purdy judge it probable that inhaled silica is slowly transformed into colloidal silica, and the present study tends in every way to support this view. In theory, the disease must be progressive for some time after the individual leaves his dusty occupation, the progression either taking the form of increased fibrosis or of increased susceptibility to tubercle infection. (The major part of the article discusses the pathological sequence of events leading to silicosis, with 3 half-tone illustrations.)

The probable path of entry for the tubercle bacillus is by aspiration. In the early stages of silicosis, the victim is more resistant than usual to the infection, but in later states he becomes more susceptible. The peribronchial lymph glands remain singularly free from tuberculosis in cases of tuberculo-silicosis, although such may also be true of uncomplicated tuberculosis.

Pneumonia is a great hazard in the earlier stages when dust inhalations block the lymphatic exits and fibrosis is slight. Thus, according to Collis, conditions favorable to pneumonia are usually unfavorable to tuberculosis, and *vice versa*.

The association with nephritis, previously noted by Collis, Gye and Purdy, is borne out in the fact that the 2 of the 12 cases here discussed died of nephritis.—T. H. Belt, Dept. of Pathology, University of Toronto, *Canad. Pub. Health J.*, XX, 10: 494–508 (Oct.), 1929.

Some Aspects of Silicosis in Industry—A group of cases recently seen were treated for pulmonary tuberculosis and silicosis was not suspected until a post-mortem examination was held on one of them. They were working in a small factory handling raw material (quartz) to be made up into a scouring powder, where even the process of filling the tins was accompanied with much dust.

There were altogether, within a period of 2 years, 6 or 7 deaths among the workers in this small factory in which not more than 15 persons—among whom 5 of the deaths which occurred were of young women—were at the same time employed.

Silicosis *per se* is an occupational risk of primary gravity, and allied with tuberculosis it forms the most fatal and at the same time most preventable group of tuberculosis cases.

It is surprising, therefore, to find how long it has taken the State to recognize these important facts, and it is only within the last few months in England that the provisions of the Workmen's Compensation Act have been applied to this occupational risk. The Dominions and other countries, notably the United States, are taking similar action.

According to Rolleston the tuberculosis affliction of the workers is not spread to their wives and families, who remained peculiarly free.—G. Quinn Lennane, *J. State Med.*, 37, 10: 602–606 (Oct.), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Nature of the Vitamin A Constituent of Green Leaves—The relation of the green color of plants to vitamin A stores has been pointed out by previous workers and in this experiment an effort was made to compare the potency of the lipoid extractive material from the green with the white or colorless leaves. Three to four times as much unsaponifiable matter can be extracted from a given weight of green as from white cabbage. The unsaponifiable material from the cabbage is incorporated in hardened cottonseed oil for feeding rabbits. It was found that the material from the green leaves was at least 10 times as potent in vitamin A as that obtained from the white leaves.

In attempting to concentrate the active principles, extracts of hot and cold alcohol and light petroleum were obtained and by the antimony trichloride color reactions it was determined that the most potent material was that associated with carotin in green cabbage. Carotin was prepared from cabbage, from spinach, and from carrots, and feeding experiments conducted with these concentrates. Carotin obtained from cabbage had the highest melting point and was presumably most nearly pure, and was active in a dose of 0.004 mg. per day. Carotin from spinach and carrots was not so pure and the positive dose required was 0.01 mg. per day. The residues from which carotin had been extracted were found to be inactive. The report by other workers of the inactivity of carotin in vitamin A is ascribed to the fact that fat other than that carrying the vitamin itself appears to be essential. The authors point to the accumulating evidence that

more than one substance can function as vitamin A, and the difficulty of associating the activity of highly colored crystals from plants with the pale substances derived from animal oil. It is possible that vitamin A activity may be regarded as inherent in a special grouping of atoms common to several individual molecules rather than to one definite molecule.—Dorothy L. Collison, Eleanor M. Hume, Ida Smedley-MacLean and Hannah H. Smith, *Biochem. J.*, XXIII, 4: 634, 1929.

A Second Thermolabile Water-Soluble Accessory Factor Necessary for the Nutrition of the Rat—The division of the vitamin B complex into the antineuritic and antipellagric factors, B₁ and B₂, is accepted and this work indicates the probability of a third factor, tentatively termed B₃. A special diet supplemented with 6 per cent marmite as the B complex source gave growth comparable to normal food. Two types of experiments are recorded, one in which the rats were fed the basal diet plus B₂ till constant weight was obtained for a 9-day period, then varying doses of the B₁ administered. These doses adjusted to pH 6.5 vary from 1/10 to 8 times the daily pigeon doses. In no case was the growth at a normal rate.

In the second type of experiment, the animals were fed at the start with the basal diet plus both B factors. In every case growth ceased or was subnormal after 4 to 5 weeks. Treated marmite retards normal growth, indicating the destruction of another factor than B₁ by alkaline hydrolysis of the marmite. Further experiments indicated

that the substance B_2 is more thermolabile than the B_1 . Discrepancies appear, the results reported here differing somewhat from facts reported by other workers, but it is pointed out that there is a possibility that the B_1 reported might have contained traces of the B_2 factor and that feeding experiments must be continued for 4 to 5 weeks to demonstrate the presence of this new factor.—Vera Reader, *Biochem. J.*, XXIII, 4: 689, 1929.

Some Evidence of the Existence of a Further Factor Necessary for Growth of the Rat—This experiment records the observations of a deficiency other than vitamin A in rats on a vitamin A-deficient diet. A vitamin A-free ration was prepared and this was irradiated in thin layers to provide ample supplies of vitamin D. This diet included a "vitamin-free casein" which was guaranteed substantially free from vitamin A. The dried yeast in the diet was also tested for vitamin B complex and it was found that 8 per cent of the yeast was sufficient for the B needs of the rat at all stages of growth.

Some of the rats on this diet failed to resume normal growth with the addition of cod liver oil, although some of the rats responded to a certain extent under such conditions. In the latter, the experiments were continued longer than the 5 to 6 weeks usually deemed necessary and these rats ceased to grow and would not resume growth with larger doses of cod liver oil, and only temporary growth resulted when the diet was supplemented with unlimited supplies of fresh watercress.

Then a product, "light-white casein," was substituted for the vitamin-free casein and rapid normal growth was resumed. However, other food substances were tested for this factor and good results were obtained with fresh milk, lettuce, fresh and dried grass clippings, ox muscle, liver and wheat em-

bryo. Milk which has been slightly heated for 15 minutes is less satisfactory, although the "light-white casein" heated in thin layers for 24 hours at 105° was just as potent as the unheated.

Attempts were made to extract the "light-white casein" with cold alcohol and with cold alcohol and ether. The extract was ineffective, while the casein which had been extracted was as potent as before. Hot alcohol and hot ether resulted in more active extracts and the residual casein appeared somewhat impaired. Hot 90 per cent alcohol extracted from wheat embryo the active factor almost completely. Hot ether extract is also active.

Additional experiments were conducted on the "light-white casein" to determine whether the factor could be associated with the vitamin B complex, and it was found to contain neither B_1 nor B_2 . The authors concluded that the factor is not vitamin E, which is not destroyed by heat as is this unknown factor. Furthermore the experimental animals indicated no shortage of vitamin E.

The authors conclude that the experiments indicate a hitherto unrecognized growth promoting factor rather than a biological inadequacy of the protein in the basal preparation.—Katherine H. Coward, Kathleen M. Key and Barbara G. E. Morgan, *Biochem. J.*, XXIII, 4: 695, 1929.

The Number and Type of Bacteria in Commercially Prepared Infant Foods—This investigation was initiated to learn the number and types of organisms found in various baby foods which may be commonly secured on the market and which are prepared from powdered milk. These proprietary compounds are arranged roughly in two groups, namely, those which serve as a complete nutrient for infants, and those which are "modifiers" to be added to cow's milk in various amounts

according to the requirements of the infant.

In examining the samples secured, the authors used standard nutrient agar and a specially prepared medium containing Difco tryptophane broth peptone and yeast extract. The latter medium is necessary to grow streptococci and those lactic acid producing bacteria which do not grow on ordinary standard agar.

Plates were incubated at 37° C. and 56° C. Five carbohydrate "modifiers" and one protein "modifier" were examined. It was found that these compounds contained organisms growing at 37° C. in numbers varying from 800 to 328,000 per gm. At 56° C. numbers of bacteria from 1,600 to 220,000 per gm. were found in these "modifiers."

Examinations were made of three synthetic compounds designed to offer complete foods for infants. These compounds were found to contain numbers of bacteria varying from 1,000 to 392,000 per gm. growing at 37° C. and from 1,000 to 128,000 per gm. growing at 56° C.

Six samples of dried or powdered milk and certain modifications of dried milk were examined. Bacteria, in these preparations, growing at 37° C. ranged from 10 to 112,000 per gm. and the number of bacteria growing at 56° C. varied from none to 600,000 per gm.

The predominating types of bacteria present in all samples were aerobic spore-formers capable of peptonizing milk. These bacteria were generally the *Bacillus subtilis* type although some organisms similar to *Bacillus cereus* were also present. The remaining bacteria isolated were cocci of miscellaneous types. It was found that the carbohydrate "modifiers" contained a higher percentage of thermophiles than did the protein "modifier" and the reconstituted complete foods.

It is pointed out that when the modi-

fiers are added to milk the numbers of bacteria per gm. are reduced owing to the dilution of the modifier with the milk. The actual numbers of bacteria present may not be excessive, but harmful effects may be derived from the protein split products produced by the proteolytic spore-forming organisms which constitute the predominating type of organisms in these products.

Investigation showed that there was no seasonal variation in the sanitary quality of these infant foods as indicated by numbers of bacteria, but that there are certain constant sources of contamination throughout the year.

It is suggested that all commercially prepared infant foods should be required to meet the following sanitary standards: (1) They should contain no hemolytic streptococci. (2) Twenty c.c. of sterile milk, when inoculated with 0.5 gm. of the infant food and incubated at 37° C. for 10 hours, should show no visible peptonization. (3) They should contain less than 10,000 colonies per gm. when the duplicate plates are incubated at 37° C. and 56° C. for 2 days, using the special medium containing tryptophane broth peptone, yeast, extract and glucose.—G. J. Hucker and Alice M. Hucker, N. Y. State Agric. Exper. Sta. *Tech. Bulletin No. 153* (Aug.), 1929.

Botulism Due to Home Canned Bartlett Pears—At Los Banos, Calif., in May, 1927, two persons, a girl of 9 and her mother, aged 27, died with typical symptoms of botulism 30 hours and 42 hours, respectively, after tasting and swallowing pieces of home canned Bartlett pears which were obviously spoiled. The toxin of *Cl. parabolitimum* was demonstrated in an enrichment culture of the gastric content of the victims obtained at autopsy.

The suspected pears were highly toxic for guinea pigs on feeding and the presence of botulism toxin type A was dem-

onstrated in the syrup. Nothing definite concerning the method of packing and sterilization could be determined, but it was established that the lid of the jar which contained the poison was bulged; the rubber ring was not tight; and the pears had an abnormal odor.

The pH of the toxic syrup was 3.86. Yeasts and lactobacilli as well as toxic and non-toxic strains of *Cl. parobotulinum* were found viable in the syrup. The m.l.d. by subcutaneous injection of the syrup for mice was 0.0005 c.c. and for guinea pigs 0.001 c.c. The thermal death time of the *Cl. parobotulinum* spores from the pears varied between 2 and 3 hours at 100° C. Examination of other samples of home canned fruit from the home of the victim showed three additional jars of pears to contain *Cl. parobotulinum* type A, identical with the organism isolated from the pears responsible for the fatalities.

By experiment it was found that the spores of *Cl. parobotulinum* isolated from the pears would resist a temperature of 100° C. for 50 minutes when these spores were suspended in raw pear juice mixed with 20 per cent syrup, the pH being 3.7. Thus, if unsound raw material carrying a mass contamination of *Cl. parobotulinum* were used, the processing time of 20 to 30 minutes at 100° C. usually followed in home canning of pears would fail to destroy the spores of the toxigenic anaerobe. The process given the toxic pears in this case was totally inadequate since yeasts and lactobacilli survived and grew.

Attempts to produce toxin experimentally in canned pears failed when pure cultures of *Cl. parobotulinum* were used. When yeasts and lactobacilli were inoculated with the botulinum organisms toxin production occurred regardless of the pH. It is concluded that the growth of the yeasts and the lactobacilli in the pears supplied the

factors which are required by the botulinum organism to germinate and to form its toxin. Pears are not subject to botulinum spoilage provided fresh and sound raw material is packed under sanitary conditions. However, a jar with a layer of mold or definite signs of fermentation may contain the deadly poison.

It is probable that certain fruits and acid vegetables owe their immunity from botulinum spoilage less to their acidity than to the absence of food substances essential to the elaboration of toxin.—K. F. Meyer and J. B. Gunnison, *J. Infect. Dis.*, 45: 135 (Aug.), 1929.

Is Irradiated Farina as Bought in the Market Enriched with Vitamin D?—This is an assay of a commercial breakfast food alleged to be "irradiated with ultra-violet rays to impart the bone-building vitamin of sunshine." Young rats between 35 and 50 gm. weight were placed on a rachitogenic diet for 18 and 21 days respectively, and at the end of that time 2 rats in each lot were killed and inorganic blood phosphorus determined and roentgenograms taken to determine the degree of rickets. The rachitic rats were kept on the test diet and compared to rats on the same diet supplemented with 2 per cent of cod liver oil, with 10 per cent of non-irradiated farina, and with 10 per cent of irradiated farina. Both farinas were bought on the open market and the 10 per cent addition was considered comparable to the amount consumed by the average child in proportion to the diet. At the end of the test periods inorganic phosphorus and ash content of femurs were determined and roentgenograms taken. The results show the rats made good gains in weight, but those on the 10 per cent irradiated farina ration showed no increase in blood phosphorus, no increase in the ash-organic residue ratio of the femurs, and X-rays show no

increased calcification in femurs. The authors conclude that the claims made for this food by its sponsors are not justified.—Frederic W. Schlutz and Mildred R. Ziegler, *J. A. M. A.*, 93: 1466 (Nov. 9), 1929.

Whole-Meal Bread—This is a brief summary and conclusions of the facts surrounding the use of whole wheat bread in the diet.—Liebig first extolled the virtues of whole wheat bread, and since 1868 it has been advocated both in Europe and America. Liebig believed it to be easily digested and more beneficial, due to the inorganic salts in the outer layers of the grain. Later Rubner showed that the proteins of bran were not easily digested and only partly assimilated. Researches in Germany in 1897 led to the conclusion that this bread was uneconomical for the military organization.

Since the wheat embryo is rich in vitamin B, this is used as an additional argument for whole wheat bread, but it is pointed out that this applies to wheat and not to rye, since in the latter industry the embryo separates with the meal and not with the bran. Whole wheat bread is advocated for relief of constipation and to obviate obesity.

Despite the potency of the wheat embryo in vitamin B, it is pointed out that to prove that a deficiency of this is responsible for constipation it would be necessary to conduct controlled experiments, with the only modification in the diet being between white bread and whole wheat bread.

There is cited the work of E. Melanby, who found a constituent of oatmeal and wheat embryo which tended

to produce rickets by interfering with bone calcification. Comparing the analyses of whole wheat, white flour and bran, the conclusion is reached that white flour is a better source of energy than whole wheat. The latter contains indigestible cell membranes which in turn enclose proteins, and about 30 to 40 per cent of the material escapes digestion. Furthermore, vegetable proteins, due to the lack of amino acids, are not rated so high as animal proteins. On a white bread diet, the percentage of total food calories lost amounts to 8 as compared to 14 on a whole meal diet.

The question as to whether it is a national economy to use whole-meal bread depends on the efficiency of the milling of the by-products. It is held that the laxative effect of whole wheat bread does not differ from other laxative material and no advantage is gained compared to the use of white bread with other laxatives as needed. It is pointed out in advocating whole wheat bread that attention should be called to the fact that experiments have so far been conducted on animals and adult males. Children are intolerant of high cellulose diets and in some the whole wheat bread is definitely irritating.

Appetite is an important factor and to many the whole wheat bread is distasteful. The obvious conclusion is that caution should be exercised in advocating whole wheat bread, particularly in the case of women and children, until such time as unbiased, controlled experiments have indicated the justification for it.—Carbohydrate Content of Foods, by R. A. McCance and R. D. Lawrence, *Report of Medical Research Council*, London, 1929, p. 53.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Why More County Nurses?—According to recent statistics country children are not so healthy as children who live in cities, and they have more physical defects. The strongest weapon to use in remedying this situation is the public health nurse. She is the missionary who can best carry the message of health into the homes and schools of America.

In one middle western state there is 1 public health nurse to every 5,092 of the urban population (that is counting the 69 industrial nurses), and 1 public health nurse to every 32,090 of the rural population, and this situation can be duplicated in any number of states.

In the *Missouri Public Health News* for November, 1929, the following reasons were given why every county in that state needs public health nurses:

1. Because 4,167 babies born last year died before they reached one year of age.

2. Because 206 young men and women died from tuberculosis last year. For every death, it is estimated that there were 10 new cases.

3. Because 406 mothers died last year from causes due to childbirth.

4. Because trachoma, a preventable disease, is the cause of blindness in one-third of Missouri's Blind Pensioners.

5. Because health examinations of Missouri school children show that 75 per cent of the children are suffering from one or more remediable physical defects.

6. Because many days of school were lost last year due to the prevalence of communicable disease. Unnecessary absentees waste the school funds.

In Missouri the average salary of a well trained public health nurse is \$1,800 a year, but this may and should

vary from \$1,500 to \$2,200 per year, depending upon the preparation of the nurse and the length of time she has been in service. In addition to salary a travel allowance of from \$35 to \$60 a month is provided when she drives her own car. Counting the expense of office space, supplies and other incidental needs, the average cost of a public health nursing service for one year is about \$2,800.—*Missouri Public Health News*, II, 46-48 (Nov.), 1929.

A Suggestion from California—It is not always recognized that an official public health nursing service frequently develops out of a service that an unofficial agency has fostered and supported until the people crave and demand it, and are willing to pay taxes for it. Oftener than not, too, the quality of the nursing service of the governmental agency depends upon the standard set by the unofficial agency which fostered the work in its experimental stage.

When an official agency does take over a nursing service, its responsibility for public health nursing in the community is not finished, but just begun, as the community health commissioner has a great opportunity open to him to stimulate the correlation of all the nursing services in the community. It is a pitiful sight to see a good sized city with several voluntary agencies carrying on nursing services, the nurses overlapping each other's work, sometimes not on speaking terms, and the city health commissioner perfectly satisfied because he employs a communicable disease nurse who goes into the homes to diagnose cases.

In contrast to this picture is the com-

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

munity whose health commissioner made arrangements to have all public health nursing agencies housed in the city hall, and was active in the amalgamation of the services. The following agencies still continued to contribute to the salaries of the nurses in this community:

The City Board of Health
The City Board of Education
The City Board of Supervisors
The American Red Cross
The State Tuberculosis Association
The Metropolitan Life Insurance Company

However, to assist in accomplishing this correlation there are the following practical considerations from the standpoint of the nurse in the field which were given by Helen S. Hartley, Public Health Nurse of Stockton, Calif., in a paper read before the Annual Conference of the California Health Officers League of California Municipalities in October:

1. An understanding health officer.
2. A supervising nurse to assist in interpreting policies and keeping the various activities balanced. Even where there are only two or three nurses, one should be assigned to this definite duty.
3. A central, workably good office from which and in which to work. The importance of being able to work comfortably in the office cannot be overestimated. Any person who has been rushing from one home to another, hearing the troubles of the people in her district, can not only work more happily, but can actually accomplish more work if given space at a comfortable desk with sufficient light and ventilation.
4. Coöperation fostered by those in charge of the budgets will fall like a mantle upon the staff, who will be chosen for their individual qualities rather than by any undue outside influence.

Helen S. Hartley, P.H.N., Health Office Direction and Coöperation, *Weekly Bull.*, Calif. State Dept. of Public Health, VIII, 42: 1 (Nov. 23), 1929.

Thirty Years of Nurses at Teachers College—The Thirtieth Anniversary of the founding of the Nursing Education Department at Teachers College, Columbia University, New York,

N. Y., was celebrated there in October by a 2-day conference, during which much honor was paid to "four of the founders" of the department. These were Mary Adelaide Nutting, Emeritus Professor of Nursing Education, whom Dean Russel characterized as the "Mother of the Nursing Education Movement"; Mrs. Helen Hartley Jenkins, who by her generous endowment made possible the Nursing Education Department of Teachers College as we know it today; Lillian D. Wald, R.N., the founder of the Henry Street Settlement Nursing Service, who led Mrs. Jenkins, through her interest in the visiting nurse, to the broader field of nursing education in general; and Dr. James E. Russel, Dean Emeritus of Teachers College, who thirty years ago dared to admit the nursing profession to the college.

The high ideals set by these four founders are being ably upheld and developed under the direction of William Fletcher Russel, the present Dean of Teachers College, and Isabel Maitland Stewart, the present Professor of the Department of Nursing Education.—The Thirtieth Anniversary of the Nursing Education Department, Teachers College, New York, *Am. J. Nurs.*, XXIX, 12: 1521 (Dec.), 1929.

The Seattle Community Nursing Service—The Community Nursing Service of Seattle has been reorganized as a separate community corporation after 10 years of growth under the Seattle Chapter of the American Red Cross. The objective of this service is to supply skilled nursing care on a visit basis to people in their homes, under the direction of licensed physicians.

The nursing personnel of the Seattle Community Nursing Service at present consists of 8 staff nurses, a supervising nurse and a director, but it is hoped that within the next 10 years the staff will be increased to 125 nurses. The staff

nurses are chosen from those graduate registered nurses who have excellent training school records and who have had postgraduate training in public health nursing.

The service of these nurses is available to every home in Seattle, both to those who can afford to pay for such a service and to those who can pay little or nothing at all. The organization feels that the greatest usefulness of its

service lies in bringing skilled nursing care to all families of moderate means who need only part-time nursing care in their homes and who do not want to be charity cases. The majority of this class in Seattle is the real backbone of the city life.—Seattle Community Nursing Service, *The Thermometer*, Washington State Dept. of Health, Division of Public Health Nursing and Child Hygiene, III, 2: 1 (Dec.), 1929.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Holiday Greetings and Appeals—Many health house organs recognized the spirit of the holidays and some sought to express their message in terms of the season. *Alameda County Public Health News*, Oakland Public Health Center: Thanksgiving design in color. . . . *The Gleaner*, Texas Bureau of Child Hygiene: a mimeographed cover design, and a Christmas Eve poem. . . . *Missouri Public Health News*, State Board: a stock cut on first page. . . . *Alameda County Public Health News*, Oakland: colored cover design and a poem. . . . *Household Nutrition*, National Dairy Council: stock borders and ornaments and holiday helps for the housekeeper. . . . *Health Bulletin*, New Jersey Tuberculosis League: a smiling youngster on cover page presenting "Merry Christmas." . . . *Crusade Lance*, Tuberculosis Society of Detroit: a cover design with poem. . . . *Baltimore Health News*, Health Department: the A. P. H. A. holiday greeting page on the cover. . . . *Pennsylvania's Health*, State Department: editorial on "The Christmas Spirit" in

terms of health, and "Keeping Christmas Merry" with timely suggestions about toys, accidents, etc. . . . *Bulletin*, Milwaukee Department: stock ornaments and a "greeting" on the cover. . . . *News Letter*, West Virginia State Department: mimeographed sketches, and "Santa's Dream" which carried good wishes to health workers. . . . *Public Safety*, National Safety Council: green Christmas trees on cover and "It's safer to do your shopping before the rush begins." . . . *Weekly Morbidity Report*, Connecticut State Department: accompanied by a green sheet, in color, with greetings and "Aid the Light of Knowledge into the Dark Corners of Your Community to Rout Superstition, Promote Public Health, Prevent Disease and Charge with Glorious Physical Well Being Through its Radiant Energy." . . . *Bulletin*, Allentown Bureau of Health: A. P. H. A. greeting page. . . . *Hoosier Health Herald*, State Tuberculosis Association: a holiday design on cover. . . . *Editor's Clip Sheet*, National Safety Council: special Christmas material. . . . *News Release* for December 31, Illinois State Department: proposal of a "Christmas health saying

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

club." . . . *Better Health*, Syracuse Department: the most pleasing of all—a silhouetted child, with greetings, also inside articles on "The Best Gift of All," and "Christmas Toys." . . . *Board of Health Bulletin*, Middletown, N. Y.: mimeographed "Merry Christmas" and a Santa. . . . *Monthly Bulletin*, New Haven, Conn.: 4 pages only, special envelope and paper, all Christmas material, in three colors, with cover design including a glorified diagram showing downward infant mortality trend, and health holiday greetings to parents and to children inside . . . several bulletins used the Christmas seal in outline . . . and of course the tuberculosis groups used much Christmas material . . . and the cancer societies . . . and money appeal letters utilized the Christmas motive. *The editor would welcome additional examples* to be included in a portfolio to be shown at Fort Worth.

"Stock cuts" are ready-made half-tones supplied by printers or by several firms which make them. "Stock ornaments" are from the varied selection available to printers who use the linotype, monotype, etc. Designs for the mimeograph may be copied or adopted from many sources.

Five Medical Societies Conduct a Joint Campaign—November, 1929, was "Health Examination Month" in New York City, but the campaign will continue less intensively throughout 1930. The Greater New York Committee on Health Examination was formed by the five county medical societies within the city; special funds were secured; and Dr. Iago Galdston of the New York Tuberculosis and Health Association was given executive direction of the effort. Posters, folders, special meetings, addresses before ready-made audiences, radio talks, letters to ministers, mention in department store advertisements, paid advertising space

in morning newspapers, a mayor's proclamation, and an essay contest in high schools, are elements of the campaign. For samples of the printed matter address Dr. Iago Galdston, 244 Madison Ave., New York, N. Y.

On Convention Programs—West Virginia Public Health Association: "The Newspaper in Its Relation to Public Health," by George Anderson.

Texas Sanitarian's Short School: "Health Aspects of Public Interest," by Dr. F. L. Hoffman; "Some Methods of Projecting Intensive Health Education," by Dr. R. J. Stroud, with discussion by Dr. W. W. Peter; Milk Playlet by School Children.

Publicity Portfolios for Conventions—The problem: how to put up, attractively and conveniently for examination, a collection of publicity materials of varied sizes, shapes, colors, etc. The solution so far as we have worked it out is explained in a memorandum which will be sent upon request. Samples to illustrate two forms of portfolio will be loaned for 10 cents and a promise to return promptly. *Address editor of this department.* The ideas described should be useful for office or lobby display of publicity materials, or for committee examination. On this page is illustrated lettering by Merwin-Davis which will give the finishing

**rural
sanitation**

touch to the portfolios. This lettering appeared on colored posters 3 by 6 inches as described in the memorandum mentioned above.

This is the symbol for the tuberculosis educational campaign, with the slogan, "Protect them from tuberculosis."

Special pictures and leaflets for Negro groups will be illustrated with this symbol.

A Nation-Wide Publicity Campaign—The spring publicity campaign of tuberculosis associations of the United States will, in April, 1930, be concerned with the childhood type of tuberculosis. Its purpose will be to tell adults responsible for the welfare of children that by the use of certain special but simple diagnostic procedures tuberculosis in its "seedling" stage, and before the appearance of symptoms, can be discovered.

The first united publicity effort of this kind was in 1928, when by means of a bludgeon blow, "*You May Have Tuberculosis*," an attempt was made to arouse the public out of its lethargy. The following year, the message was more gentle and optimistic, centering about the slogan, "Early Discovery, Early Recovery—Let Your Doctor Decide." The time seems right, therefore, to concentrate attention on a method of anticipating the disease in children and providing safeguards designed to prevent its development into pulmonary tuberculosis, or old-fashioned consumption.

The campaign is sponsored by the National Conference of Tuberculosis

Secretaries, under the leadership of the National Tuberculosis Association. As some of the facts about the childhood type of tuberculosis are still in controversy, much effort was expended by clinicians (called in for the purpose more than a year in advance of the campaign) so to frame the message as to be truthful and at the same time understandable and pragmatic. The subject, childhood tuberculosis, gives opportunity to revive the old story of tuberculosis prevention from a fresh aspect and to give publicity to the results of several significant research studies now under way.

Production of the materials began in the summer of 1929, and samples were in the hands of state and local associations by November. These include a brief leaflet for parents and a more extensive treatment of the subject in a 16-page illustrated booklet, bearing the title, "*Do Children Have Tuberculosis?*" designed for the intelligent parent and teacher, an illustrated manual on the diagnosis of childhood tuberculosis for physicians, a 24-sheet billboard poster, smaller posters of various sizes, lecture slides, electrotypes, and a mo-

tion picture produced by Eastman Teaching Films. The emblem or symbol of the campaign will be the portrait of an attractive child. The slogan is, "Protect Them from Tuberculosis," supplemented by:

Keep them away from sick people.
Insist on plenty of rest.
Train them in health habits.
Consult the doctor regularly.

A special feature for this year will be the leaflets and posters for Negroes, which are the same as the others in text but illustrated with the head of a Negro child.

Each state will organize its own campaign, just as it does the Christmas seal sale. The National Tuberculosis Association supplements this with national publicity. The Metropolitan Life Insurance Company will again devote its usual advertising page, which reaches potentially 21 million people, to an illustrated treatise on childhood tuberculosis. Contacts will be made with national headquarters of fraternal organizations, insurance companies, women's clubs, etc. Articles and cuts will be offered house organs and trade journals, and a series of syndicated newspaper articles will be offered for release.

Last year, the National Tuberculosis Association prepared more than 6 million pieces of literature, 116 reels of motion pictures and 830 electrotypes. This was supplemented by additional material produced by state and local associations, by 1 million special leaflets prepared by John Hancock Life Insurance Company, and by other publicity features. Demands for literature from insurance and fraternal organizations greatly exceeded the ability of the National Tuberculosis Association to furnish the materials requested. No effort was spared, of course, to enlist the coöperation of health departments, schools and civic organizations.

Actual results of previous campaigns

defy exact measurement. While the amount of materials distributed, the number of lectures given, the amount of newspaper space secured, and so on, can be measured, these give no indication as to the desired end results in terms of the number of people who were persuaded to "let the doctor decide." Samplings of certain localities showed that clinic attendance and sanatorium applications were increased, and private physicians reported an increased number of patients desiring to know whether or not they might have tuberculosis. But the sum total of information conveyed or action stimulated is elusive. A device for measuring the results of an otherwise ordinary and calculated publicity campaign will probably prove to be the weakness of this effort as it was in previous ones; therefore, suggestions are eagerly invited.—H. E. Kleinschmidt, M.D.

The President Believes in Health Education—An extract from the health section of President Hoover's annual message to Congress, December 2, 1929:

The organization of preventive measures and health education in its personal application is the province of public health service. Such organization should be as universal as public education. Its support is a proper burden upon the taxpayer. It cannot be organized with success, either in its sanitary or educational phases, except upon public authority. It should be based upon local and state responsibility, but I consider that the Federal Government has an obligation of contribution to the establishment of such agencies.

Offered to Professional Public Health Schools—The two-session program at the Chicago A. P. H. A. meeting on "A Health Education and Publicity Program" seems to offer material of value in the teaching of public health. Reprints have been provided by the Department of Surveys and Exhibits, Russell Sage Foundation, 130 East 22d St., New York, N. Y. Copies have been of-

ferred to public health and social work training schools for free distribution to all students of public health administration or other subjects where the reprint would be useful.

The reprint includes the following: "Why Have a Plan?"—Mary Swain Routzahn; "Objectives of Publicity—On What Basis Are They Selected?"—Howard W. Green; "Audiences—How to Select and Classify Them"—Marjorie Delevan (May, 1929); "The Facts—How to Decide What Is to Be Told"—C.-E. A. Winslow; "The Approach—How to Decide on the Motives for Conduct to Which an Appeal Will Be Made"—Franklin Fearing (June, 1929)—A. J. P. H.

A Prerequisite to Effective Publicity—

We are urged not to forget that the final test of public information is that as a result of being informed or convinced individuals act in quite specific ways. The speaker or writer who has these objectives clearly in mind is less likely to wander from the point or indulge in wordy generalizations. It seems probable that educational programs would have more vitality and a closer relation to the thinking of everyday human beings if those who planned them were fully aware of the individual responses necessary to make broad programs come true. If each effort of publicity were tested by the question "What effect should this have on the behavior of those who are exposed to it?" much writing, speaking and graphic presentation of ideas would be revised to become more simple, direct and practical in content.—

From "The Aims of Social Hygiene Publicity," by Mary Swain Routzahn, *J. Social Hyg.*, Feb., 1929.

Diphtheria "Talkie" Trailers—

For several years the baffling problem of motion picture distribution has been met by the New York State Health Department through the use of trailers, pictures running approximately two minutes which a considerable proportion of theatre owners are willing to run in the regular programs.

This same possibility appealed to the Diphtheria Prevention Commission of the New York City Department of Health. The first production was a 300-foot "talkie" trailer in which Health Commissioner Wynne was presented delivering a talk on diphtheria of 575 words. The 50 prints were distributed from the executive offices of the theatre circuits to practically all houses in the city equipped for sound pictures.

Later four silent trailers, each about 125 feet and running a minute and a half, were put into circulation. Here are the four messages:

A message from Commissioner Wynne himself. He invites us into his office, where we watch him write it. Then we see a group of happy kiddies whom he is calling upon us to protect.

Happy, healthy children playing in the snow outside. Jolly Jack Frost comes a-jumping into the house and on the frost-flowered window pane writes an important message with an icicle point.

East side, west side, all around the town, children playing merrily excepting one little sick child who watches them from her window until her view is cut off by a timely message.

In a beautiful flower garden surrounding a pond of water-lilies (this subject is in color), we see a group of pretty children pointing to a message in the rippling water at their feet.

For a copy of the letter describing the four trailers to theatre managers and of Commissioner Wynne's talk, address the Commission at 505 Pearl St., New York, N. Y.

Headline Producing Copy—News releases containing material for headlines that will attract the attention of newspaper readers are illustrated in the following extracts from the output of the Illinois State Department of Public Health:

Dec. 4: Detecting crime among the germ population by the finger print method is now a major function of the State Department of

Health. No less than 354 examinations of this kind are done daily and 17 per cent show evidence of guilt. These facts are disclosed in the annual report of Dr. Andy Hall, State Health Director, which was handed to the Governor here this week. It showed that the laboratory, referred to as the finger print bureau, did 129,296 tests during the last fiscal year and that 22,421 incriminated numerous bacteria bent upon the destruction of people all over the state. Specimens reached the laboratory from every county in the state ranging in number from 3 for Edwards to 12,624 for Kane. . . .

Dec. 11: With contagious diseases now sending more than a thousand school children to bed weekly in Illinois Dr. Andy Hall, State Health Director, declared here today that absence from the classrooms is a medical rather than a disciplinary problem and recommended the employment of nurses as truant officers. Carefully kept records disclose that fully 90 per cent of absenteeism in the schools is due to illness of one sort or another and that efficient health service will reduce considerably the amount of sickness in the school population. "The six diseases of smallpox, measles, scarlet fever, whooping cough, diphtheria and chicken pox are now causing 2,000 fresh cases of illness weekly in Illinois and no less than one-half of the cases are among children of school age. All are quarantinable and cause extended absence from school. . . .

Dec. 18: Comparing the person who refuses or neglects to report a case of contagious disease to "hit-and-run" motor car drivers who fail to report accidents, Dr. Andy Hall, State Health Director, announced here today that a new national system of communicable disease notification is in process of organization by the federal government and that Illinois has applied for admission. Every case of communicable disease must be reported to Washington under the new system, which is a voluntary enterprise, but states where reports are seriously incomplete and delinquent will be left outside the new registration area. "Increasing travel tends to multiply enormously the opportunity of spreading contagious disease," said Dr. Hall. "As transportation facilities increase in speed and comfort this danger increases because individuals with mild attacks or in the incubation period are more apt to attempt journeys which promise quick and easy passage." . . .

Dec. 26: With mortality rates, barometer of winter health conditions, duplicating almost

exactly their behavior of this season last year, Dr. Andy Hall, State Health Director, expressed here today the fear that a return wave of influenza is in the making. Case reports of pneumonia which have jumped from 225 to 350 per week within a month suggest the same possibility. The tendency of influenza to travel in waves of 33-week periods makes another epidemic due in Illinois toward the end of February. "A sharp rise in the death rate at this time of year, especially if it includes a significant increase in deaths from pneumonia, suggests the possibility of influenza" . . .

The quotations above show one-third or more of each release. *Copies free.*

BELIEVE IT, OR NOT

Many state and local health reports have neither a table of contents nor an index!

An important city health agency report includes 91 headings—without index or table of contents—and many of the headings refer to topics not to be expected in a health report!

A few annual reports of nonofficial agencies do not carry the name of the city unless, possibly, it is buried incidentally somewhere in the text!

NEW PUBLICATION

After 10 or 11 years the *Railroad Man's Magazine* (280 Broadway, New York, N. Y.) has been resumed by the Munsey organization—probably an opportunity for national agencies and others with health information which should appeal to this particular audience.

WORDS

Every man is a dictionary, and his definition of words is ruled by his education and experiences.—From *Goblin Market* by H. de Vere Stackpoole.

When you wish to say that it is raining, say "It rains."—Credited by *Advertising and Selling* to Boileau in *L'Art Poétique*.

BOOKS AND REPORTS

Microbiology—By *Benjamin Franklin Lutman*. New York: McGraw-Hill, 1929. 459 pp. Price, \$4.00.

Among the many books on microbiology written by non-medical men, this is one of the best. As long as the author sticks to his own subject, his material is excellent, but when he wanders into the domain of medicine, he is out of his element, and makes statements which are not in accordance with facts.

Some of his quotations are deplorably old. In discussing tuberculosis, for example, he gives material published in 1911, and there are a number of other references equally ancient. Just why a book of this type should consider the cure of tuberculosis is hard to understand. In discussing other diseases there is a similar lack of exactness. The discovery of diphtheria antitoxin is credited to Roux and Martin. Von Behring is not even mentioned, though he had priority in the work. Anthrax vaccine is spoken of as "serum." In the Schick Test we are told to inject "two cubic centimeters of a dilution of diphtheria toxin under the skin of the arm"—advice which is wrong from every standpoint and, if followed, might lead to severe injury or death.

The illustrations are good and abundant. The printing is good for the most part, but there seems no excuse for the misspelling of such well known proper names as Vaughan, and none for putting Koch ahead of Pasteur in credit for establishing the relation of germs to disease. If the medical discussions had been omitted, the book would be very much better. The fondness of non-medical men for discussing medical subjects is not to be com-

mended. Apart from these the book is good. A little learning is a dangerous thing. M. P. RAVENEL

An Adventure with Children—By *Mary H. Lewis*. New York: Macmillan, 1929. 250 pp. Price, \$1.75.

This is an adventure of a dozen or so years' duration in which the author conducted a "school" (perhaps this word has too many hidebound connotations—maybe we should say, "conducted the lives of children") according to progressive principles. Besides its interesting material the book holds one's attention because of its style and because we feel the constant influence of the author's enthusiasm.

The basic principle upon which the school was conducted, "do" rather than "don't," prevails in the writing of this book. It is the opposite of the "Uncle Tom's Cabin" or "don't" type. It makes little reference to the condition which is being met, but presents the solution.

In reading this account one can but be aware of the dynamic rôle of the leader whether it be in molding the opinion of a board of trustees, in raising money, in persuading parents to submit their children to an experiment, stimulating a group of teachers, or in dealing directly with the children. The great value of this forcefulness is apparent in the rapid development of the school. Its weakness appears in the panic of insecurity which caused the school to retrench when its leader was taken sick. So much of the personal enters into this adventure that one would not be satisfied that he understands it without knowing considerable of the life history of the author. Per-

plantation in the South, miles away from the nearest physician, has left in the mind of the reviewer a belief that a book of this kind may still serve a useful purpose. Accepting this as a fact, the work of Dr. Skrainka can be recommended. It is more sound and reliable than most of the general class to which it belongs. M. P. RAVENEL

The Science of Nutrition Simplified.

A Popular Introduction to Dietetics
—By D. D. Rosewarne, M.R.C.S.,
L.R.C.P. St. Louis: Mosby, 1929.
314 pp. Price, \$3.50.

In the profusion of books on nutrition this one has the distinction of being scientifically sound and free from faddism. It is a straightforward, unembellished account of modern dietary principles. No one can complain about its accuracy, but a popular book needs a little more than that to make it appealing to the lay reader. This book lacks color in its style, though not in its cover, which is a jaundiced looking affair. It is well printed, with large type on good paper, and has an index. Anyone who wants a simple and trustworthy, if not tremendously inspiring, book on nutrition will find this one of value.

JAMES A. TOBEY

Nature Study and Health Education

—By Alice Jean Patterson. *Normal, Ill.: McKnight and McKnight. 5 Vol.* Price, \$.80–\$.96.

Health habit training is pleasingly woven into nature study in this series of school books. The first volume simplifies the problems of the teacher of the first and second grades by giving her definite lesson units. Health workers will welcome the use of these publications, for they will tend to stimulate instruction in hygiene.

Hygienists may question some of the proposals. For instance, the suggestion that the school teacher make the health examinations "in schools where there is

no nurse or physician," might lead to complications. It would seem that the same methods utilized to make nature study absorbing to the youngsters might have been used to more effect in health habit training. Tooth brush drills, health rhyme chanting, admonitions to eat spinach seem uninspiring compared to the fun to be had in keeping a balanced aquarium.

The volumes are written in appropriately simple language and printed in large type so that they can be read by the pupils of the progressive grades as class room exercises. Each succeeds in reaching the interest level of the class intended in so far as nature study is concerned. There is not an equally well planned progressive appeal to the health interest. The same ten health habits crop up each year. It would seem that by the sixth grade the children would fairly groan at the repetition of "1. Clean persons—hands, nails, face, ears"—and so on for the entire ten.

The merit of combining so effectively these two subjects, thus simplifying teaching schedules, far outweighs occasional criticisms of content, which as a whole is excellent.

RAYMOND S. PATTERSON

Medical Leaders. From Hippocrates to Osler—By Samuel W. Lambert, M.D., and George M. Goodwin, M.D. Indianapolis: Bobbs-Merrill, 1929. 331 pp. Ill. Price, \$5.00.

The authors have given us a readable and valuable contribution to the history of medicine. They have adopted the method of dividing history according to the various phases of development, and under these, considering some of the great figures who have had much to do with the development of the science.

The selections they have made are good as far as they go, and the facts correct. While one must naturally

grant to writers some freedom in the selection of their heroes, notable omissions open them to criticism. Auenbrugger and Laennec are justly included in the sketches, but one looks in vain for the name of Villemin, who first showed us that tuberculosis was communicable, and that the various types were all manifestations of the same pathological process. Surely he deserves a place in a book on Medical Leaders.

The weakest part of the book is that devoted to the modern period, in which there are a number of incomplete and unsatisfying statements, as well as actual errors. It is stated that Agramonte was given yellow fever by the bites of mosquitoes, and recovered. All available authorities state—what the reviewer believes of his own knowledge to be correct—that Agramonte was an immune.

The book is well printed, and can be commended to the average physician and reader who does not care to delve too deeply into medical history.

M. P. RAVENEL

Creative Activities in Physical Education—*By Olive K. Horrigan.* New York: A. S. Barnes and Co., 1929. 405 pp. Price, \$2.00.

This book is a timely contribution to the present trend in education to correlate various units of study in the minds of children. Physical education, which has been to many merely a means of developing the physical well-being of the child, is here made a means to an end of vivifying poetry, music, history, and manners and customs of world peoples. At the same time, the primary function of physical education is kept steadily in mind and its value emphasized because of the self expression and bodily control developed in these new avenues of its application.

The classroom teacher is kept in mind also and is given excellent mate-

rial in verse, music, and directions for dancing and games, as a basis for trying out each of the suggestions offered. In addition, very comprehensive references are given in each connection. The whole book is made attractive by clearness, practical understanding of the teacher's problems, and a delightful sympathy with a child's imagination.

LENN A. L. MEANES

Health. What Everyone Ought to Know—*By Oliver T. Osborne, M.D.* Baltimore: Charles C. Thomas, 1929. Price, \$2.50.

This book belongs to the better class of those which have been written in such numbers during the last few years for the instruction of the public. It goes somewhat into physiology, and takes up nutrition, growth, foods, clothing, exercise, etc. The ground is well covered, and in an exceptionally clear fashion. It does not go into the treatment of disease, though general advice is given concerning first aid and simple care of some of the skin eruptions. The sections on the selection of a physician and on quackery are good.

There are a few mistakes, such as crediting the isolation of cocaine to an American chemist; and omissions, such as a discussion of alcohol, which is especially noticeable since there is a special chapter devoted to habits in which the narcotics are well handled.

The jacket gives a list of questions designed to direct the reader's attention to important subjects. There are no illustrations, but there is a very good index.

The book comes from the new publishing house of Charles C. Thomas, and its make-up deserves more than passing mention. On the page following the index, we are given the history of the printing, design of cover, name of the type and the paper. It is a delight to read a book so well gotten up.

M. P. RAVENEL

Three Minute Medicine. *A Series of Brief Essays on Popular Medicine—By Louis R. Efler, M.D.* Boston: Badger, 1929. 453 pp. Price, \$3.00.

This volume, which may be called "Tabloid Medicine" (no disparagement intended), is the outcome of an editorial in the *Saturday Evening Post*, which charged that while physicians were alive to the educative powers of the press, they did not know how to use it, or to express themselves in the racy English which was needed. The Toledo Academy of Medicine responded to this by appointing an Education Committee, and through its work there was created a daily medical column in the *Toledo Times* printed on the editorial page under the heading "Said by Toledo Doctors." The Academy of Medicine has thereby sponsored the material in this book.

Some 200 subjects are considered, running all the way from short biographies of the fathers of medicine down to halitosis. Some 25 papers give "Anecdotes and Curiosities." The articles average about 400 words.

The book is eminently entertaining, and the facts in the main are sound, though the ideas expressed in some of the articles, "Ptomaine Poisoning," for example, are out of date and incomplete. The truth is told about medical fads and superstitions. Controversial matters, such as credit for the discovery of ether anesthesia, are fairly stated. This interesting experiment we judge has been entirely successful so far, and we wish it could be extended to every city in the United States. The printing and make-up of the book are excellent, the paper light, and we hope for it a large circulation. Even doctors will find many interesting anecdotes unknown to many.

M. P. RAVENEL

Pathogenic Microorganisms. *A Practical Manual for Students, Physicians, and Health Officers—By William H. Park, M.D., Anna W. Williams, M.D., and Charles Krumwiede, M.D.* (9th ed. rev.). Philadelphia: Lea and Febiger, 1929. 819 pp. Price, \$6.50.

A book which has gone through nine editions has proved its value. In the present instance the authors have continued to add new material as it became available, bringing the text up to date.

In the sixth edition the practical application of serums and vaccines was transferred to a special section, known as Part III. In the present edition the earlier arrangement, which placed the practical application of our knowledge under the individual diseases, has been returned to, which, in our judgment, is a distinct improvement.

The new work on streptococci, yellow fever, and other subjects has been included, and there is a section on the use of BCG by the mouth in the immunization of children against tuberculosis. The newer precipitin tests are also included and discussed.

There are some peculiar statements, as on page 696, where we are told that the *Aedes aegypti* (properly *aegypti*) has been found as far north as Charleston, S. C. As it has been abundantly proved that in this country, at least, this mosquito is the only means by which the disease is transmitted, one cannot help wondering as to the origin of the epidemics in Wilmington, Norfolk, and even Philadelphia.

The book is well printed and put together, though there are still some errors in the index and elsewhere. Altogether we consider it the most useful single volume for students. M. P. RAVENEL

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Nebraska—The object of Nebraska's recently organized Public Health Association is to "protect and promote public health by the closer correlation of all health activities, fostering and supporting constructive legislation, and aiding in the dissemination of correct information with regard to public health." The work of the State Bureau of Health is organized under four divisions: vital statistics, child hygiene, venereal diseases, and laboratories—each with its own director.

Heart disease with 1,840 deaths leads the list of causes of death, with cerebral hemorrhage and apoplexy (1,266) and cancer, all forms (1,257), following.

One of several amendments to the vital statistics statute by the 1927 Legislature authorizes the State Department of Public Welfare to make a charge of 50 cents for a certified copy of the record of a birth, death, marriage or divorce. At the request of any parent or guardian a certificate giving information relative to parentage and date of birth is furnished free of charge for school purposes or for securing employment.

Health schools for women were held in 36 communities, giving 4 lessons each in prenatal, infant and child care, and in prevention and control of disease. Eighteen groups of high school girls received instruction in 4 lessons on infant and child care. Lesson outlines and bulletins added value to this instruction. During the biennium there were 156 Child Health Conferences, in which 5,514 children were given a complete physical examination, with 13,094 remediable defects found. A total sum of \$221,635.99 was paid in mothers' pensions by 89 of the 93 counties in the state during 1927. This money was

distributed among 1,173 mothers and involved 3,322 children.

At the request of the secretary of the Department of Public Welfare, a 3-month survey was made to show the needs of juvenile court and probation development, especially in the rural counties of the state, and to stimulate local interest in the extension of these agencies. A recommendation for County Welfare Boards, with one trained worker in the smaller counties, seems the only way to obtain satisfactory probation service and to cover other important welfare needs. An educational campaign, to be carried on by the Child Welfare Division of the State Department of Public Welfare, is suggested to impress upon the respective communities the responsibility which they have toward their youth and their families who need help.

Readable Reports—No longer are annual health department reports confined to mere tabulations of births, deaths, marriages, and a statistical record of accomplishments during the year, with but meager, if any, interpretive comments upon the material presented. With communities becoming more and more health-minded, health officers have adopted modern publicity methods in report writing and are finding their clear and business like reports in great demand.

Graphic and pictorial presentation of the development of activities and the trend of mortality rates become effective tools by which the health officer acquaints the public with happenings in the field of public health. "Palo Alto Public Health Milestones" aptly illustrates the newer method of charting the growth of health work in a city. Any

number of interesting variations of this method might be worked out by health administrators and used advantageously in an annual report or other health education publications.

Health education is relatively new as a recognized health department activity, and the annual report offers an excellent opportunity for community education concerning the work of the department as a whole.

Analyzing health facts and discussing them in language that can be readily understood by the layman as well as the professional, now becomes a necessity. Business groups, keenly alive to the economics of public health work, and seeking convincing evidence of progress in the reduction of death rates from preventable causes, are impressed with diagrams showing the decline in typhoid deaths after the installation of a safe water supply or the adoption of a sound milk ordinance. Similarly, the value of diphtheria immunization work becomes an established fact upon the presentation of charts showing the death rate from diphtheria before and after immunization campaigns began.

The 1928 annual report of "Public Health in Cattaraugus County, N. Y." is one of several excellent examples of a "readable report." Well printed, with sufficient illustrations and diagrams, with just the proper amount of tabular material and with chapter headings and sub-headings that have a popular appeal, this report serves the purpose of education as well as a chronicle of activities and accomplishments during 1928. Its style deserves imitation.

Illustration used in the 1927 Palo Alto Annual Health Department Report, and reprinted in *Health Officers' News Letter*, A. P. H. A., 4, 11 (Nov. 22), 1929.

Cattaraugus County, N. Y.—The roll of honor of health reports for 1928 will include that of Cattaraugus County.

The report is characterized by careful preparation and editing, excellent arrangement, with headings and sub-headings, good printing in readable type, attractive illustrations, with charts, graphs, and photographs accompanied by interesting descriptive text.

There are 3 distinct autonomous groups together representing a coöperative county effort to promote public health work. These groups include the official county department of health, including local health officers; the official county agency for health supervision of school children; and the local voluntary health agencies in various parts of the county. There are 73 physicians and 36 dentists for an estimated population of 72,851.

Bureaus that have functioned within the county unit as a part of the health department include the Bureau of Tuberculosis, with a medical director; the county laboratory, with a medical director, 3 technicians and 2 laboratory workers; the Bureau of Public Health Nursing, with a director, an educational director, a social service consultant and 14 staff nurses; and the Bureau of Maternal, Infant and Child Hygiene, with a medical director. The Bureau of Statistics has a statistician in charge. In addition, there were 6 stenographers and clerks and a sanitary inspector on the staff, beside the full-time medical health officer. The budget for the year amounted to \$108,000, of which \$56,000 was from county and state funds and \$52,000 from the Milbank Memorial Fund.

This county reports a birth rate of 18.5, about one-third of the births occurring in hospitals. A death rate of 13.8 and an infant mortality rate of 70 are recorded. Of 97 infant deaths, 68 occurred before the infant was a month old. There were 21 cases of diphtheria, with 1 death. The parents of the family where the fatal case occurred had been urged by the public health nurse to

have toxin-antitoxin for the children, but, as in so many cases, the matter had been put off because diphtheria was not present at the time. There were 35 deaths from tuberculosis during the year, giving a specific rate of 47 as compared with a rate of 76 in 1918.

Health education, according to the report, is effectively extended from neighbor to neighbor as a result of personal contact with some branch of the county health service, as well as by more formal means. Members of the staff gave 135 addresses to groups numbering 5,600 people, while newspapers published over 8,700 health articles.

Milwaukee, Wis.—One of the 10 chapters of the 1928 report of municipal government and activities of the City of Milwaukee deals with public health. This city of approximately 550,000 people reports a birth rate of 22.3 per 1,000 population, a death rate of 10.9, and an infant mortality rate of 70 per 1,000 living births. Of the 846 infant deaths during the year, 477 or over one-half occurred during the first 30 days of life. To decrease this infant mortality rate it is suggested that a more intensive prenatal program be put into effect.

Several new full-time positions were created during the year. Milwaukee now employs a full-time director of health education who develops the publicity and educational work through the four divisions of news material, lectures, publications, and exhibits. Other full-time positions include the home nursing instructor, the nutrition instructor, and the instructor in social hygiene. The budget of the health department, apart from the amount appropriated for the maintenance of South View hospital, allows 90 cents per capita for preventive health work.

One of the most gratifying accomplishments in the health field in Milwaukee during 1928 was the reduction in both diphtheria case and death rates

from 757 cases with 56 deaths for 1927 to 382 cases with 35 deaths in 1928. On the other hand, epidemics of influenza and pneumonia were more serious in this city during 1928 than any year since 1918.

A total of 29,756 visits, of which 758 were school children and 17,197 well babies, was made at the child welfare clinics during the year, as compared with 25,679 in 1927. In these clinics, toxin-antitoxin was administered to 3,532 children; while 788 were vaccinated, and 2,165 had complete physical examinations. Physical examinations of 62,011 school children were made by school physicians. Defects found numbered 55,976 and 22,556 corrections of these defects were recommended. The nurses of the child welfare division made 56,979 child welfare calls during the year; of these, 13,335 were upon preschool children. Preschool activities advanced greatly during 1928, when 4,304 preschool children visited the clinics, an increase of 1,295 over last year.

R. E. W.

Los Angeles, Calif.—The health officer's report for the year ending June 30, 1929, contains a table of contents at the front and an alphabetical index at the back. The following significant statements appear in a letter of transmittal.

The effectiveness of the health officer's work is increased or diminished by the attitude, knowledge and sympathies of his Board of Commissioners. It is essential that health commissioners be men of broad human sympathy with a real interest in the problems of the wage earner and the poor. They must be men who understand and believe thoroughly in the principles and practices of public health as taught and laid down by the American Public Health Association and the U. S. Public Health Service, for it is according to these principles and regulations that the health officer must work.

This city of an estimated population of 1,350,000 reports an average death rate for the last 5 years of 10.47 and an

the normally healthy child from the ailing one, stimulate the question of what constitutes "normal" health.

FORDYCE, A. D. Borderline Problems in Childhood. *Brit. M. J.*, 3591: 791 (Nov. 2), 1929.

Iodine as an Influenza Prophylactic—Twenty-three schools in which the children were given iodine "blocks" were closed a total of 73 days. Twenty-three control schools (in which the children got no iodine) were closed for 155 days on account of epidemic sickness, usually influenza. Write your own annotation.

FRASER, K. Effect of Iodine in Reducing Loss of School Attendance from Epidemic Sickness. *Med. Off.*, 42, 22: 242 (Nov. 30), 1929.

Infectivity of Chicken Pox—Chicken pox apparently is infectious for not more than 24 hours preceding the eruption, and probably ceases within 10 days. Convalescent serum affords a high degree of protection.

GORDON, J. E., and MEADER, F. M. The Period of Infectivity and Serum Prevention of Chicken Pox. *J. A. M. A.*, 93, 26: 2013 (Dec. 28), 1929.

Washing Water Filters—The results of washing rapid sand filters with varying velocities of wash water are studied, and a formula is suggested to determine efficient washing rates.

HULBERT, R., and HERRING, F. W. Studies on the Washing of Rapid Filters. *J. Am. Water Works Assn.*, 21, 11: 1445 (Nov.), 1929.

Convalescent Serum—Evidence of the rôle of convalescent serum in the prevention of measles after exposure and in preventing paralysis in poliomyelitis is subjected to a critical review. The prophylactic value of measles serum seems assured, but the case for poliomyelitis serum is more difficult to establish.

KELLOG, W. H. The Present Status of Con-

valescent Serum Therapy. *J. A. M. A.*, 93, 25: 1927 (Dec. 21), 1929.

Rural Influenza Studies—An outbreak of influenza in two isolated communities gave a unique opportunity for an epidemiologic study. The incubation period was usually 2-3 days. Nearly half the families in one town contracted the disease.

KRAMER, S. D. A Study of an Influenza Epidemic in Two Small Isolated Towns. *J. Prev. Med.*, 3, 6: 433 (Nov.), 1929.

Rural Health Work—Enlightening indeed to complaisant provincials is this detailed report of the extent of rural health administration in which the U. S. Public Health Service coöperates.

LUMSDEN, L. L. Coöperative Rural Health Work of the U. S. Public Health Service in the Fiscal Year 1929. *Pub. Health Rep.*, 44, 49: 2985 (Dec. 6), 1929.

Cell Biochemistry—This paper appears to be a very profound dissertation on the biochemistry of the cells and tissue. Undoubtedly it will prove intensely stimulating to readers of the *JOURNAL* who may be at home in biochemistry. To others it is so much Greek.

PETERS, R. A. Coördinate Biochemistry of the Cell and Tissues. *J. State Med.*, 37, 12: 683 (Dec.), 1929.

Hypertension in Relation to Age and Sex—As a sudden rise in the incidence of hypertension occurs at the time in each sex which coincides with the age at which involution of the glands of internal secretion begins, this fact seems significant.

RISEMAN, J. E. F., and WEISS, S. The Age and Sex Incidence of Arterial Hypertension. *Am. Heart J.*, 5, 2: 172 (Dec.), 1929.

Height and Weight in Negro Children—The variation in the height-weight-age relationships in white and negro children is set forth in tables com-

piled from a very large number of measurements.

ROYSTER, L. T., and HULVEY, C. N. The Relations of Weight, Height and Age in Negro Children. *Am. J. Dis. Child.*, 38, 6: 1222 (Dec.), 1929.

Tuberculin Skin Reactions—Less than half as many children in America today give a positive response to the intracutaneous injection of tuberculin as did the children in the series of published European studies. This makes the tuberculin reaction the more important, and it should be applied to every child who is underweight, anemic, languid.

SMITH, C. H. Tuberculin Skin Reactions. *Am. J. Dis. Child.*, 38, 6: 1137 (Dec.), 1929.

Milk Regulations—That the courts continue to be liberal in upholding all reasonable regulation of milk production by the constituted health authorities is the conclusion of this brief review.

TOBEY, J. A. The Legal Phases of Milk Control. *Pub. Health Rep.*, 44, 51: 3110 (Dec. 20), 1929.

Open-Air Schools—Attractively illustrated, this architect's description of the Derbyshire (England) open-air elementary schools will prove exceedingly valuable to American sanitarians concerned with this special health project.

WIDDOWS, G. H. The Derbyshire Open-Air School. *Med. Off.*, 42, 22: 241 (Nov. 30), 1929.

NEWS FROM THE FIELD

WEST VIRGINIA PUBLIC HEALTH ASSOCIATION

THE following are among the resolutions passed by the West Virginia Public Health Association, at its meeting in Morgantown, W. Va., November 26, 1929.

RESOLVED that an intensive effort be made to secure an increase in the annual appropriation made by the State Legislature for the State Health Department in order that the department may be enabled to extend its activities to a greater extent throughout the state, and be it further

RESOLVED that the necessity for an increase be brought to the attention of the County Courts of the state and also to the State Budget Commission, as outlined in our president's address.

RESOLVED that there be a continued effort made to standardize the methods of administration of public health work and looking toward securing a more permanent tenure of office for health officials.

RESOLVED that the West Virginia Public Health Association secure from the other state associations affiliated with the American Public Health Association an expression of opinion regarding the advisability of requesting the American Public Health Association to provide some channel through which the papers presented at the meetings of the various state associations may be published, so that they may be made available to the members of all affiliated public health associations.

NEW JERSEY PUBLIC HEALTH AND SANITARY ASSOCIATION

THE Fifty-fifth Annual Meeting of the New Jersey Public Health and Sanitary Association was held on December 6 and 7 in Asbury Park, N. J.

The following officers were elected for the ensuing year: D. C. Bowen, Asbury Park, President; Samuel B. English, Glen Gardner, First Vice-President; Samuel L. Salasin, M.D., Atlantic City, Second Vice-President; F. J. Osborne,

Health Officer, East Orange, Third Vice-President; Edward Guion, M.D., Atlantic City, Secretary; H. B. Baldwin, East Orange, Treasurer; James E. Brooks, C.E., Glen Ridge, Chairman of the Executive Council; Carl T. Pomeroy, Montclair; Mrs. Lenore Y. Wiley, East Orange; I. W. Knight, Pitman; A. S. Fell, M.D., Trenton, and William B. Palmer, East Orange, were added to the Council. Representative to the American Public Health Association, Edward Guion, M.D., Atlantic City, and B. H. Obert, Asbury Park, alternate.

This society is now regularly incorporated under the laws of New Jersey.

CHILDREN'S BUREAUS, GERMANY

THE first statistical review of the activities of the official children's bureaus of Germany has been recently published.

A national system of children's bureaus was established in Germany by legislation which was enacted in 1922 but which did not come into effect until 1924. The bureaus supervise children placed outside their homes, hold the guardianship of children born out of wedlock, administer public aid to dependent minors, supervise neglected children, and share in probation work and in the enforcement of child labor laws. A recent statistical report of the work of the bureaus shows that on March 31, 1928, there were more than 1,200 children's bureaus in Germany outside Saxony, where this work is carried on by public relief agencies. On that date the bureaus had under supervision more than 544,000 children under 14 years of age in foster homes and were serving as legal guardians of 560,000 children, most of whom were

born out of wedlock. Special supervision was being exercised over 66,000 children who though living with their parents were in danger of becoming neglected or delinquent. The bureaus were also doing probation work with 48,000 juvenile delinquents, in most cases in coöperation with private probation agencies.

S. CHANNING CHILD HOSPITAL OPENED IN VIENNA

THE gratitude of a retired New Jersey business man, who was cured 3 years ago by Dr. Adolf Edelmann, is responsible for the opening of a new important world hospital for cancer and internal diseases in Vienna. It will be known as the S. Channing Child Hospital and Research Institute and will occupy the building of the famous private clinic "Pelikangasse." The new institute is placed under the direction of Dr. Edelmann. There will be many free beds.

The hospital will have the latest radium and biological laboratories and a staff of 30 research physicians. Dr. Edelmann has been a research worker in Vienna for 18 years and, like Mme. Curie, is of Polish birth.

CONGRESS FOR SEX RESEARCH

THE Second International Congress for Sex Research will be held in the House of the British Medical Association, Tavistock Square, London, August 3-9, 1930, under the presidency of Professor F. A. E. Crew, of Edinburgh. Both in membership and in importance it is expected that this meeting will notably excel the First Congress, held in Berlin in October, 1926. Those who are interested are requested to write Professor Crew, The University, West Mains Road, Edinburgh.

The organization and purposes of the Congress can be fully served only by having all of the many aspects of sex

research properly represented among the papers read at the London meeting. To American workers it is highly desirable that American investigations and investigators should be adequately represented at London—particularly since few from this country attended the First Congress.

An American committee has been formed for the purpose of securing a maximum participation in the Congress by workers in this country. The members of this committee, representing biology, medicine, psychology, sociology and anthropology, are: Dr. Oscar Riddle, Chairman, Dr. A. A. Brill, Dr. Calvin P. Stone, Dr. William F. Ogburn and Dr. Clark Wissler.

HARVEY W. WILEY RESIGNS

ON January 1, 1930, Dr. Wiley became Director-emeritus of the *Good Housekeeping* Bureau of Foods, Sanitation and Health. Dr. Wiley has been connected with this service since 1912, and resigns because of his great age—83. The Bureau was created for him so he might wage war upon impure foods. He was formerly chief of the U. S. Bureau of Chemistry, which in 1928 was abolished and supplanted by the Bureau of Soils and Chemistry.

TEXAS ASSOCIATION OF SANITARIANS

IN convention assembled at Edinburg, Tex., December 5, 1929, the Texas Association of Sanitarians selected the following new officers for the ensuing year, 1930: President, Dr. H. K. Read, Houston; First Vice President, H. W. Van Hovenberg, Texarkana; Second Vice President, Dr. Y. J. Aiken, Lubbock; Third Vice President, C. N. Shepherdson, College Station; Fourth Vice President, Marguerite Cunningham, Fort Worth; Secretary, E. G. Eggert, Austin. Dr. H. K. Read, the new President, is Supervisor of Hygienics in the public schools of Houston.

It was unanimously decided to hold the 1930 annual short school at Amarillo the first part of September and also hold the business session jointly with the American Public Health Association convention, with which the Texas Association is affiliated, at Fort Worth the last week in October.

Approximately 250 were registered for the meeting and declared this one of the best sessions ever held. Dr. J. R. Mahone is the retiring president.

Some of the resolutions passed were as follows:

WHEREAS, the activities of the State Board of Health and the staff of the State Department of Health have been of great benefit to the state in the prevention of sickness; and

WHEREAS, they have labored diligently during the sessions of this school for the advancement of sanitation in Texas, especially in connection with the standard milk sanitation program, mosquito control, and in water and sewage purification; therefore be it

RESOLVED, that this Association endorse their activities, and further, that steps be taken to bring these accomplishments to the attention of the next Legislature with the request that more adequate appropriations be made for the support of an ample health program for the State of Texas.

WHEREAS, the Republic of Mexico, through its Public Health Service, has been so gracious as to have a representative attend and participate in our sessions in person of Dr. Toribio Gracia; and

WHEREAS, this visit has been instrumental in furthering friendly relations and a closer understanding in health matters; and

WHEREAS, the ground work has been laid through this visit for a joint international health meeting in connection with the American Public Health Association convention in 1930 at Fort Worth, with the possibility of a side trip excursion to Mexico City; therefore be it

RESOLVED, that this Association express its thanks to the government officials of Mexico and especially Dr. Toribio Gracia for his contributions and his visit.

WHEREAS, the American Public Health Association, in convention assembled in Minneapolis in October, 1929, selected Fort Worth, Texas, for the 1930 annual convention place; and

WHEREAS, this decision was made at the urgent request of the combined efforts of various Texas groups, including the Association of Sanitarians; therefore be it

RESOLVED, that this Association officially go on record here as pledging its full support and coöperation in making the 1930 convention a memorable success.

POPULAR SCIENCE MONTHLY PRIZE

AN annual award of \$10,000 and a gold medal for outstanding scientific achievement, to be made first in September, 1930, has been established by *Popular Science Monthly*. A committee composed of 24 scientists will select the first winner from among those who accomplish outstanding work in the year ending June 30, 1930.

This award was created "to heighten the interest of the American people in those conquests of the laboratory and the workshop which benefit the entire community."

NOBEL PRIZE IN MEDICINE

THE Caroline Institute of Stockholm, Sweden, announced that the Nobel Prize in medicine for 1929 has been awarded to Dr. C. Eijkmann of the University of Utrecht, Holland, jointly with Frederick Gowland Hopkins, professor of biochemistry at the University of Cambridge, England. This prize was awarded to them for their excellent work on vitamins.

THE FIRST INTERNATIONAL CONGRESS ON MENTAL HYGIENE

THE First International Congress on Mental Hygiene will be held in Washington, D. C., May 5-10, 1930, with headquarters at the Hotel Willard. President Hoover is Honorary President of the Congress. The American Psychiatric Association and the American Association for the Study of the Feeble-minded will hold their Annual Meetings in conjunction with the Congress.

The *Proceedings* containing papers delivered will be available by applica-

tion to John R. Shillady, Administrative Secretary, 370 Seventh Avenue, New York, N. Y.

Clifford W. Beers of the National Committee for Mental Hygiene is Secretary General of the Congress. Mr. Beers's book *The Mind That Found Itself* is now in its 15th edition.

AUSTRIAN HEALTH DEMONSTRATIONS

THE health demonstrations which have been conducted in Austria during the past five years by the Commonwealth Fund have been concluded. Among the permanent results are more than 80 child-health centers, located in every Province of Austria and enrolling more than 42,000 mothers and children.

which will be continued under the supervision of a national administrative committee with government appropriations to take the place of Commonwealth Fund support. A large proportion of the money expended in Austria was used in providing educational opportunities for physicians and health workers occupying strategic positions and in grants to the institutions and activities best able to contribute to further strengthening the public health program.

NEW MEXICO

THE state of New Mexico has been admitted to the U. S. Birth and Death Registration Areas for the year 1929.

PERSONALS

W. C. SIEKER, principal of the Milwaukee Vocational School, Milwaukee, Wis., died on December 2, 1929. Mr. Sieker is a member of the American Public Health Association.

B. L. ARMS, M.D., formerly state health commissioner of Florida, is now county health officer of Idaho Falls, Ida. Dr. Arms is a Fellow of the A. P. H. A.

JAMES C. HARDING, JR., is now associated with Barker & Wheeler, an engineering concern of New York, N. Y.

DR. L. G. BEAN has been appointed as Chief of the new Bureau of Dental Hygiene of the State Department of Health of Ohio.

DR. J. A. FRANK, Chief of the Division of Hygiene, State Department of Health, Ohio, died on December 5.

DR. CLARENCE FLOYD HAVILAND died of pneumonia in Cairo, Egypt. He was the Superintendent of the Manhattan State Hospital for the Insane on Wards Island, New York.

DR. FRED L. ADAIR has accepted the chair of gynecology and obstetrics at the University of Chicago Medical School. Dr. Adair was formerly with the University of Minnesota Medical School.

C. ST. CLAIR DRAKE, M.D., formerly Associate Field Director of the Committee on Administrative Practice of the American Public Health Association, is now Managing Officer of Jacksonville State Hospital, Jacksonville, Ill.

CONFERENCES

Feb. 18, American Conference on Hospital Service, Chicago, Ill.

May 5-10, First International Congress on Mental Hygiene, Washington, D. C.

June 6-14, National Conference of Social Work, Boston, Mass.

FOREIGN

May 19-21, Second International Malaria Congress, Algiers, Algeria

June 4-9, Congress of Royal Institute of Public Health, Portsmouth, England

June 21-28, Royal Sanitary Institute, 41st Congress and Health Exhibition, Margate, England

EDUCATIONAL DIRECTORY

MEDICAL BIOLOGY COURSE

Four year course leading to
B.S. degree

Well equipped laboratories of the College, the Michigan State Department of Health and large city hospitals are available. Prepares for laboratory positions in chemistry, serology, bacteriology and pathology.

Catalog sent on request. Address Professor of Bacteriology and Hygiene, Michigan State College, East Lansing, Michigan.

Course in Veterinary Medicine

Full four year college course leading to degree D.V.M. For information, address Dean of Veterinary Medicine, Michigan State College, East Lansing, Michigan.

WELLESLEY COLLEGE GRADUATE DEPARTMENT HYGIENE AND PHYSICAL EDUCATION

A two years' course for the training of teachers of Hygiene and Physical Education. Prerequisite—Bachelor's degree. Leads to Certificate of Department of Hygiene and Physical Education or to Master of Science in Hygiene and Physical Education. Address Chairman, Graduate Committee, Wellesley College, Wellesley, Mass.

Some Special Problems in Atmospheric Pollution*

ABEL WOLMAN, F. A. P. H. A.

Chief Engineer, Maryland State Department of Health, Baltimore, Md.

ONLY a few of the evils attendant upon our industrial evolution and urbanization of life are discussed in this paper. The problems selected are chosen as typifying some of the objectionable features of atmospheric adulteration which have confronted our department in recent years. The examples cited are illustrative only. They may be multiplied in many directions. Aside from their technical implications, their significance in relation to current administrative health practice and to the important question of public attitudes is briefly commented upon.

CARBON MONOXIDE HAZARDS IN THE STEEL INDUSTRY

As a basic industry of the modern world, perhaps none surpasses the manufacture of steel, either in the application of its product or in the employment of workers. As one of the oldest industries, it also brings with it complicated problems of hygiene in many instances unrecognized or at least inadequately understood. One of these lies in the control of the detrimental effect upon exposed operators of carbon monoxide pollution of the atmosphere.

As an illustration of the hazard involved, the conditions at a single steel plant are briefly presented. At this plant, 6 blast furnaces are available, 5 of which are used continuously. Each is charged with 450 tons of coal and produces daily about 160,000 cu. ft. of gas, which is collected from the tops of the furnaces by means of 4 take-down pipes, discharging into a dust separator where the large particles of

* Read at a Joint Session of the Laboratory and Public Health Engineering Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

coke and coal are removed by gravity. From these the gases are passed into a washing chamber where the finer particles of suspended matter are removed. After drying in rotary driers, a portion of the gases is utilized to operate the steam boilers. The rest passes directly to the engine room to be utilized in Bethlehem internal combustion engines. There are 6 twin engines, each driving electric generators having a rated capacity of 400 kw. The exhausts discharge through water seals into a main header, from which the exhaust gases pass by way of a tunnel to a 100-foot stack discharging into the atmosphere. At the time of our investigations 10 men were employed around these engines. They were required to inspect the gas seals in the cellar under the engines about four times a day. This cellar was poorly ventilated and men consigned to this work were gassed from time to time, due presumably to leaks at the gas seals or in the main header. Most of the gas poisonings occurred in these gas engine works.

At the coke oven unit of the works an average of about 320 men is regularly employed. These ovens are charged from the top every 8 minutes. Gases from this unit are conducted to a recovery plant where ammonia, tar, naphthalein, oil and other by-products are removed. After this treatment the gas is passed to Baltimore for use. Records of the company show only 3 cases of gas poisoning at this unit in the 8 years preceding. These coke oven furnaces are not housed, and employees are in the open at all times.

Gas passed on to Baltimore is pumped by 8 Ingersoll Rand electric drive booster pumps. Three men work in 8-hour shifts each at this plant, with an extra man during the daylight shift. No cases of gas poisoning have ever been reported from this unit.

The whole plant was supplied with a great number of Burrell, McCay and Gibbs, and other makes of gas masks. Oxygen tanks for artificial respiration were located at various stations about the works. Each year 20 or more men were given a 2 weeks' course of instruction in artificial respiration methods and other work of this sort by a representative from the U. S. Bureau of Mines.

A record of gas poisoning cases in the year 1926 is shown in Tables I and II. A total of 337 cases occurred in a little over 9 months. A large majority of these were termed "gas headaches" by the corporation physician. This indicated that the employee had applied at the dispensary for treatment for headache caused presumably by carbon monoxide poisoning. Other cases were termed "gas exhaustion" and were of a more serious nature. Most of these were brought to the dispensary by ambulance and many required treatment with oxygen. Some were incapacitated for a few hours, others for several days.

TABLE I
CASES OF "GAS HEADACHES" REPORTED IN A STEEL PLANT

July	25	5	4		1 4 days
August	36	2	3		
September	25	8	4	1	1 1 day
October	3				

The majority of these cases of carbon monoxide poisoning occurred at the gas engine unit in the basement below the operating floor. Intensive surveys at this unit revealed faulty water seals, leaks in the gas exhaust main, and other mechanical defects which would occur from time to time in the engine proper. Repair work in these connections was responsible for numerous cases of so-called gas exhaustion of a serious nature. Several deaths resulted during repairs to the gas collection main. In all instances, according to the superintendent, the men who died were equipped with masks which apparently failed to protect under the existing concentration. Steps were immediately taken to correct faulty gas seals, to repair gas engines, and to redesign certain portions of the equipment. Windows near the roof of the building were redesigned for better circulation, and radiators were installed for heating some of the air in winter in order to effect more rapid movement and increase circulation.

The Department of Health established various stations throughout this unit for determining relative concentrations of carbon monoxide and made various suggestions for ventilating the basement section by means of exhaust fans.

TABLE II
CASES OF "GAS EXHAUSTION" REPORTED IN A STEEL PLANT

Date 1926	Total Cases	Number of Cases of Varying Intensity			
		Ambulance	Bed	Oxygen	Miscellaneous

					1 1st stage
					1 3 weeks
August	4	2	2		
September	4	4	3	3	
October	2	2	1		1 mild

Results of these tests showed that concentrations of carbon monoxide varied from 1 to 4 parts per 10,000. The higher concentration was usually noted in the basement near the seal pots under one or another of the engines. Owing to the design of the building and the layout of pipes and conduits, the elimination of gases from this point was very difficult. Ventilating fans were finally successful in greatly reducing the concentration of carbon monoxide. Preceding this ventilation work every effort was made to stop all leaks from the seal pots and other places. New engine cylinders were installed and one furnace was completely rebuilt. During a temporary shut-down serious leaks in the exhaust tunnel were found. After the elimination of these leaks, there was a noticeable decrease in all forms of gas cases. The company spent considerable money in general overhauling of gas engines and in corrections of gas leaks.

Coincident with improvements in atmospheric conditions, marked increase was noted in electric power production from the generating apparatus served by these engines. It was not until investigations were begun in detail, however, that it was found that the chief source of carbon monoxide contamination at this unit was located where the main exhaust pipe entered the tunnel. An estimation of loss due to leakage at this point was \$1,000 per year. In addition it was found that the tunnel was in a much worse condition than had been anticipated and would eventually have endangered the entire structure. Actual cost of rebuilding this tunnel exceeded \$20,000. It was ultimately completely lined with fire brick because of its waterproofing quality and its resistance to high temperatures.

TABLE III

TOTAL NUMBER OF CARBON MONOXIDE CASES AFTER IMPROVEMENTS IN GAS
ENGINE UNIT, DURING 1928

Month	Cases

May	0
June	1
July	2
August	1
September	2

Correction of numerous defects in the apparatus comprising this unit of the plant and much redesigning of ventilating equipment had a marked effect in reducing carbon monoxide contamination of the atmosphere. Precautions against gassing were simultaneously stimulated by the safety department with equally desirable results. For the 6 months following completion of work at the gas engine house only 8 cases of carbon monoxide poisoning were recorded (see Table III).

BENZOL POISONING IN THE STEEL INDUSTRY

Only rarely in recent years have serious unhygienic results been found in connection with the production of benzol as a by-product in the treatment of coke oven gases. During the past 2 years only one such death has occurred at a steel plant in Maryland, in June, 1927, and, strangely enough, the victim was a foreman in the benzol plant, thoroughly familiar with the hazards involved and completely cognizant of the precautions to be observed. He was killed while working on condenser equipment, having entered the top of the condenser without a gas mask before the benzol gases had had time to escape. He disobeyed regulations familiar to himself—the wearing of a gas mask and the steaming out of the condenser before entry.

HYDROGEN SULPHIDE IN THE ILLUMINATING GAS INDUSTRY

It is interesting to point out the close interconnection in problems of atmospheric pollution of a number of allied industries. In the discussion on the production of blast furnace and coke oven gas, reference was made to the fact that a considerable number of materials are extracted during the purification of the gases. After this, the bulk of the coke oven gas is sold, in many instances to gas companies who in turn convert the material to domestic and industrial uses for heating, lighting and power. The gas companies for a great many years have been concerned with the removal of hydrogen sulphide and cyanogen gas from such coke oven gases. In most instances, this has been accomplished by passing the gas through iron oxide boxes where the hydrogen sulphide is removed in the presence of the iron catalyst.

Within 7 or 8 years, however, due largely to the efforts of the Koppers Company of Pittsburgh, a new system of purification, known as the Liquid Gas Purification Method, has been developed. Such a plant was installed by the Koppers Company in Maryland, in 1923, in a territory outside of Baltimore adjacent to a semi-urban population of considerable size. The process is designed to remove the hydrogen sulphide from coke oven gas which is to be used for domestic and industrial purposes.

Raw coke oven gas is passed through a tower while soda ash solution is sprayed downward through it. This solution absorbs a large portion of the contained hydrogen sulphide. The gas is then passed on to the plant of the gas company for further treatment before being distributed into the city mains.

The spent soda ash is blown with air, and the occluded hydrogen sulphide is released and passed into the air from the top of a 200-foot stack. It soon became the source of considerable nuisance, in 1924.

The complaints were not only with respect to objectionable odors, but to distinct irritations of nose, throat and eyes in persons living in the vicinity of the plant. The writer can testify as to the validity of these complaints, owing to the distinctly objectionable and severe irritations of the nose and throat experienced during inspection.

As a result of the activities of our department during 1924, temporary measures were taken to alleviate the nuisance by the installation of burners in the lower portion of the purification tower, raising the temperature of the gas and causing it to rise to a greater height with a consequent greater dispersion and dilution. The unheated hydrogen sulphide has a tendency to descend, due to the fact that its specific gravity is higher than that of the surrounding atmosphere. Observations indicated only temporary abatement of the nuisance.

Laboratory experiments by the Koppers Company culminated in the construction of a large experimental plant designed for a complete elimination of the hydrogen sulphide discharge.

The general principles of the supplemental unit involved treatment of the exhaust gas from the stack by means of specially prepared iron turnings, together with a patented catalyst.

Under experimental operations, slight odors were noticeable at 25 feet from the plant with burners at the base of the stack consuming about 750,000 cu. ft. of gas per month. The new process was considered to be functioning satisfactorily, but was incapable of handling the entire volume of gas discharged from the scrubber process. Twelve thousand cu. ft. per day were being treated, about 50 per cent of the estimated capacity of the experimental plant. The combined process made use of two towers, one designed to scrub the incoming gas with soda ash solution and the other to aerate and release the occluded hydrogen sulphide. The unit designed to split off the sulphur from the released gas by aeration in the presence of a catalyst was capable of caring for only about 25 per cent. The remainder of the hydrogen sulphide was therefore discharged into the atmosphere, and continued to create a nuisance.

Efforts were made to eliminate difficulties experienced due to poisoning of the catalyst by cyanogen. One of the two towers was utilized for removing the cyanogen before removal of hydrogen sulphide in the experimental plant. During all this experimental work only slight decrease of odor nuisance was obtained and efforts were made to dilute the released hydrogen sulphide by the installation of an additional blower pending enlargement of the experimental plant and perfection of a more efficient catalyst.

Complaints were brought to the attention of the State Depart-

ment of Health, and efforts were made to speed up the enlargement of the experimental plant. Increased heating units and additional blowers were resorted to by the company pending enlargement.

Perfections in experimental operations were later completed and the treatment plant was enlarged to handle the entire volume of stack exhaust gases, thus eliminating entirely the discharge of hydrogen sulphide. The plant operating at full capacity adequately removed 6 tons of hydrogen sulphide and 2 tons of hydrogen cyanide per day. Sampling stations were established and relative concentrations of hydrogen sulphide were determined by this bureau. The results are shown in Table IV.

TABLE IV

HYDROGEN SULPHIDE DETERMINATIONS AT GAS PURIFICATION PLANT

July 17, 1925	Per cent
East of scrubbers	0.000315
West of scrubbers	0.00315
800 feet west of plant	0.00126
1,500 feet west of plant	0.00126
July 21, 1925	
700 feet north west of plant	0.029
1,500 feet west of plant	0.006
800 feet east of plant	0.008
30 feet east of scrubbers	0.003

NOTE: Toxic minimum is given at about 0.005 per cent by U. S. Public Health Service (C. W. Mitchell, *U. S. P. H. Reports*, 39: 1, Jan. 4, 1924).

With the elimination of the discharge of any hydrogen sulphide into the atmosphere the nuisance was completely abated. At this time the construction of a treatment plant of a size designed to handle the entire intake of coke oven gas was under way. The resulting sulphur sludge is handled by spreading in the open in layers about 8 inches thick. Filter pressing of the sludge was found to be unsatisfactory.

The Koppers Company made some interesting observations in connection with the above problem, on the concentration of hydrogen sulphide in the air in the vicinity of sulphur springs and baths in this country, well known as health resorts, and the amounts and effects of concentrations of the gas in the air at these are interesting. These observations have not been published, and are referred to with the company's consent. At several of the resorts the concentration of hydrogen sulphide was very slight owing to the fact that the springs were covered and enclosed in box-like structures. At some which were covered only by a canopy, the atmosphere showed above the surface of the spring concentrations of 50 p.p.m. Observations in some of the sulphur baths indicated no objectionable effects where the concentration of hydrogen sulphide was below 10 to 15 p.p.m.

At one resort, which showed almost 15 per cent of hydrogen sulphide by volume in the spring water, the water was aerated before being used in the baths because it was found that the hydrogen sulphide affected the eyes of the attendants. At present in the bath houses the concentration of hydrogen sulphide ranges from 30 to 50 p.p.m. The odor of hydrogen sulphide was not very pronounced due to the fact that these high concentrations paralyze the olfactory nerves. All of the bath attendants wore goggles and still complained of conjunctivitis. The U. S. Bureau of Mines has tentatively established 50 p.p.m. as the minimum concentration causing sub-acute symptoms of hydrogen sulphide poisoning and conjunctivitis.

Similar difficulties with high concentrations of this gas have been experienced in the oil industry.

PHOSPHORUS POISONING IN THE MANUFACTURE OF FIRE WORKS

Strange as it may appear, instances have occurred within the past 5 or 6 years, in which this most horrible of atmospheric pollutions has been the cause of damage. Fortunately, several plants at which such poisoning has taken place in Maryland have abandoned the use of phosphorus. The chemicals usually employed at present are mercury sulphocyanide, barium nitrate, dextrose, aluminum oxide, iron oxide, strontium nitrate, potassium nitrate, sulphur, sesqui-sulphide of phosphorus, carbon, etc. White phosphorus was at one time used extensively, but was discontinued about 3 years previous to this survey.

Snakes were manufactured as follows: Mercury and nitric acid were mixed. A paste was obtained by mixing this product with sulphocyanate, and dried in air driers. It was transferred to pellet machines and molded into pellets or tablets. Only one operator is required, who is under instructions to wear gloves and a mask. The latter was only occasionally used. Adequate precautions were taken in respect to ventilation, fire, explosive and storage hazards. Housing and handling of explosives were in separate buildings.

There have been no cases of chemical poisoning since the abandonment of white phosphorus. Previously, 2 cases were recorded.*

CONCLUSIONS

Aside from the technical aspects apparent in the above reports, certain philosophical conclusions appear to be warranted. In dealing with these and other similar situations, one cannot escape the conclusion that the disabilities inherent in any of these examples of atmospheric pollution result largely from the ignorance and inertia of

* *Industrial Poisons in the United States, 1925, Macmillan.*

both employer and employee. The employer frequently ignores the possible effects of the compounds used in, and resulting from, industrial processes, largely because his attention is directed primarily toward production and distribution, and only secondarily toward the human physiological factors. Too frequently, processes and materials are introduced into common industrial and domestic use without regard to the health hazards involved. Recent difficulties with household refrigerants are another example of the unfortunate results of these general attitudes. The employee, on the other hand, too often does not use such safeguards as are frequently put within his reach. Nowhere more than in industry is the truth of the axiom, "familiarity breeds contempt," more completely confirmed.

These attitudes point clearly to the necessity not only of official health department control over such hazards, but of educating employer and worker alike in the potentialities and methods of avoidance of danger. As in so many other fields of hygienic endeavor, knowledge and its application are the solutions to the risks of atmospheric pollution.

ACKNOWLEDGMENTS—The writer wishes to record his appreciation of the aid of S. T. Powell and M. H. Coblenz, of the Bureau of Sanitary Engineering, in the preparation of field reports and office data respectively, in connection with the studies presented in this paper.

Child Hygiene in Rural Districts of Sweden

A CONSIDERABLE part of child hygiene work in the rural districts of Sweden is done by the local public health officer, assisted in some places by midwives and visiting nurses who are also employed by the government.

Lecture courses on child hygiene for mothers are an important phase of this work. Because the long distances are an obstacle to attendance, these courses are sometimes intensified, each course lasting only 3 or 4 days of 3 or 4 hours each. They are usually accompanied by exhibits. The courses are advertised in advance through the local newspapers, and through circulars distributed among the school children. As the rural mothers show little inclination to go out in the evening, more active methods for securing attendance seem to be advisable. Good results have been obtained in some districts by nurses and midwives in public service visiting every young mother in order to persuade her to attend.

It is very difficult to do anything for the preschool child on account of the long distances between the farms. The problem is easier with school children for whom physical examinations are a common practice. The importance of coöperation between home and school as a means of improving the child's health is realized, and in some places the home environment is investigated. Evening meetings are arranged for the parents at which individual cases and general child hygiene are discussed by the public health officer. These meetings are accompanied by musical entertainments, recitations, and story telling. The teachers in rural districts also take part in the work by teaching the children habits of hygiene.—*Tidskrift för Barnavård och Ungdomsskydd*, Stockholm, No. 5, 1929.

Difficulties Encountered in the Control of Mechanical Refrigeration*

JOEL I. CONNOLLY, F. A. P. H. A., THOMAS J. CLAFFY,
AND JOHN J. AEBERLY

*Bureau of Sanitary Engineering; Division of Plumbing and New Buildings;
and Division of Ventilation and Industrial Hygiene, Department of Health,
Chicago, Ill.*

THE health hazards of mechanical refrigeration have begun to receive the attention which their importance warrants. Previously the fire and explosion hazards alone were considered in formulating regulatory measures.

Ten deaths and 30 non-fatal cases of injury occurred in Chicago during one year, all of them due to the action of gases used in mechanical refrigerators, without the occurrence of a fire or explosion. The former lack of any clear conception on the part of the general public of even elementary principles of this type of refrigerating apparatus has resulted in a feeling that the cold is produced by electricity, and when the fact is mentioned that toxic gases are employed, it not infrequently causes surprise.

People have taken toxic gases into their homes without question because they have felt that the makers of the equipment would not knowingly expose the public to undue danger. Certain manufacturers have deliberately chosen to use methyl chloride as a refrigerant because it was less toxic than other commonly used gases. The 10 deaths were caused by it. Though less toxic than some others, it is both anesthetic in action and less evident to the senses, and therefore stole upon its victims unawares.

No attempt will be made to go into the question of relative toxicity of various refrigerants. A good deal of information has been accumulated, but it is not so simple a matter to determine how the available knowledge may be applied to preventing unnecessary deaths and injuries, and still retain a valuable feature of modern life.

The public health engineer must find ways and means of administrative control. One of the greatest difficulties in all public health

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

work is to find a practicable method of applying new knowledge and discoveries. If our practice could keep pace with our knowledge, death rates would be lower and certain diseases would soon disappear from the face of the earth.

All refrigerants in common use are toxic. Animal experimentation has given an idea of toxic limits for the various gases employed. Our problem is to prevent leaks of quantities sufficient to produce poisonous concentrations in the air or in foods and drinks. Of course, the ideal solution would be to find a non-toxic refrigerant that could be used at the temperatures and pressures desired. The discovery of such a refrigerant is not likely to occur in the near future because all gases, except the mixture we call air, are toxic in some concentrations.

The importance of this problem is not fully realized either by the public or public health administrators generally. The population in Chicago exposed to the hazard of methyl chloride poisoning from refrigerator leaks is small as compared with that exposed to illuminating gas poisoning, or to typhoid fever through contamination of a large milk supply or of the water supply. Last year we had 16 deaths from typhoid fever in a population of more than 3,000,000, and 10 deaths in an equal period from methyl chloride poisoning in a population of users estimated not to exceed 50,000. Thus it may readily be seen that the problem is a comparatively important one.

No one realizes more fully than the public health worker the immense value of adequate refrigeration in conserving health by the preservation of food; but we cannot allow ourselves to be misled by the arguments of those who advocate cheap refrigeration at the expense of safety. It is as illogical to permit unsafe mechanical refrigeration in order to reduce its cost to the poor classes, as to permit a poor man to drive an automobile without brakes for the reason that brakes cost money.

The number of deaths alone does not give a true picture of the importance of the problem presented by defective mechanical refrigerating equipment. Some of those who have been poisoned, but did not die, have not yet recovered, and there is some question as to whether they ever will be restored to complete health and usefulness. Therefore, we must prevent small leaks that menace health in addition to larger leaks that may cause death.

It will be appreciated that if a system of piping and equipment which contains a refrigerant be made absolutely tight, even though a very dangerous and toxic gas is used, no health hazard will result. This, however, is impossible. At no time have we found a type of construction and workmanship which would assure this. Therefore,

the control of this practice resolves itself, first, into the design and installation of systems that are as nearly leak-proof as possible, and second, into providing maintenance that does not permit of leaks. The design and construction of these systems should be controlled: (1) At the plan examination desk; (2) By follow-up inspections which should be made to assure that the systems are installed in accordance with the plans that have been approved.

In most states there should be no difficulty in providing legislation regulating the submitting of plans to the local administering officer for approval. He should be provided with a competent staff to examine the plans and determine in advance of construction the possibility of leaks, and he should not approve them until he is satisfied beyond a reasonable doubt that the design assures the absence of any dangerously large leak. A thorough inspection should be made before the apparatus is put into use to determine the quality of workmanship and materials as well as the design of the system.

The most difficult problem in the control of this practice is maintenance. Experience has shown that there are numerous conditions which invariably contribute to leaks in refrigerating systems, such as: vibration and settling of buildings, shrinkage of timber and similar materials, and expansion and contraction of rigidly anchored piping systems. In addition we have tampering with the systems by inexperienced persons.

There should be little difficulty in developing control of the design of a system as well as its installation in accordance with the approved plans. This follows very closely the established practice in many cities in installing plumbing and ventilating facilities. On the other hand, the prevention of leaks and their speedy correction is a problem that is somewhat different from that in the control of the other mechanical features of buildings. Our problem is to determine the extent and location of the leak, and the means to use for correcting the condition.

A leak in a system containing a refrigerant may be detected: by the odor which the refrigerant may have, due either to its inherent properties, or to an added odorous substance; by some chemical process which detects minute concentrations in the air envelope; or by a chemical process which will detect larger concentrations when applied in close proximity to the leak. It is also possible to determine whether a system leaks by application of a pressure test.

There is no odorous substance that we know of that can be used with entire satisfaction in a refrigerant. To show some of the difficulties encountered in testing odorous substances, we cite an example

which obtains in the refrigerating industry. Sulphur dioxide has been used as a detector with methyl chloride gas. The boiling points of these substances, while nearly the same, are not alike. Further, when the gases are liquefied they vary considerably in density. It should be apparent to the student of physics and the man who has knowledge of the refrigeration cycle that a mixture of 10 per cent sulphur dioxide and 90 per cent methyl chloride will not be found at different times in that ratio throughout the system. Our tests have demonstrated this to be true. The question arises—if the odorous gases escape more quickly than the non-odorous, will a condition eventually result that no longer insures the expected protection? We know of no method that can be used for detecting minute quantities of refrigerants when there has been an escape of gas into the air envelope surrounding the system, except in the proximity of the leak.

In the case of sulphur dioxide and methyl chloride we have field methods which will detect very small quantities of gas when we are able to approximate the location of the leak. These, however, do not lend themselves to solving the problem of hidden leaks to the extent that the health officer desires, because of the concealed or inaccessible spaces in which the piping and the joints are frequently placed, such as the furred-in spaces in buildings.

In attempting to apply a pressure test when the existence of leaks is suspected, it is necessary to pump down the whole system—which requires several hours—to get the refrigerant out of the evaporator and the piping, and this must be done to a point where there is no liquid left and the entire system registers a sub-atmospheric pressure. If this is not done, the liquid remaining will eventually evaporate and give misleading results.

It is not uncommon in the industry, when the pressure test is applied after the system has been pumped down, to use an inert gas, such as nitrogen, to refill for test purposes. This, however, is costly. If air is used, extreme care must be taken to dry out all of the moisture, especially when refrigerants which become corrosive in the presence of moisture are used, such as sulphur dioxide. To assure the absence of any dangerous leak, it is necessary to hold the system under pressure for at least several hours, and better for 24 hours. After this, the test gas will be let out and the refrigerant replaced. This takes additional time before the system can be put back into normal operation. Throughout this entire period the tenants will be without mechanical refrigeration. The confusion and costliness of such a process can be visualized; so here again we meet with a possible but rather impracticable method of control.

Our experience in trying to locate leaks, even in systems that have been known to leak, has shown that it is often little short of impossible to find them. We have also found that the cost of locating and repairing a small leak is so great that the tendency of service men has been to let it remain, compensating for the loss of refrigerant by placing large amounts in a liquid receiver, and making this much larger than would be necessary in a tight system. In fact, some systems are so constructed and located that unless they have a very large leak, about the only reasonable service that can be rendered is the replacement of the escaped refrigerant. As all refrigerants have toxic properties, we are concerned with their continuous escape in the home even in small quantities. There must be a development of the mechanical features in mechanical refrigeration in the home that will give the health officer an effective control at a reasonable expense to the community and to the building owner, and thus assure safety.

There are several methods which the industry could use in helping the health officer to develop this control. The most satisfactory arrangement found thus far, based on our present knowledge, is to place the system containing the refrigerant, which we refer to as the primary, inside a second gas-tight system vented to the outside air, which we call the secondary. Refrigerants leaking from the primary system are conducted to the outside air by the secondary system and prevented from reaching habitable spaces. Such a double system has been built by a Chicago company at our suggestion and is operating satisfactorily under test conditions at the factory.

To assure the continued tightness of the secondary system, it is evident that it should be built in such a way that a suitable pressure test can be applied easily, requiring very little time and attention and without interfering with refrigeration. There are many designs that may be used for secondary systems, any of which would give the health officer the necessary control of mechanical refrigeration in the home where toxic gases are used as refrigerants.

In conclusion, it should be emphasized that the present rapid expansion of the use of mechanical refrigeration is creating a new and serious public health problem. There is no desire on the part of public health workers to set up a number of varied standards in different cities and states, which, if done, would preclude standardization and mass production of apparatus. We seek to agree upon, first, a proper standard of safety for health as well as for life, and second, an adequate means for securing and maintaining that standard, by suitable plan examination, inspection and tests of the physical equipment.

Problems of Cancer Mortality Statistics*

H. E. ROBERTSON, M. D.

Section on Pathologic Anatomy, The Mayo Clinic, Rochester, Minn.

TO the average observer, and this would include most physicians, there would seem to be no problem. Cancer is cancer and as a rule is readily recognized as such. The primary site is ordinarily easy to determine, either by direct observation or by accurate clinical deduction. Its responsibility for the death of its host is in most cases plainly manifest. Its duration, at least clinically, is usually fairly definitely ascertainable and its general characteristics stand out about as clearly as any other of the innumerable phenomena associated with the death dealing diseases. Why, carps the critic, waste time discussing a branch of vital statistics so well oriented and on the whole so satisfactory, when other much more complex questions are crying aloud for clarification and solution? He may add that although the peculiar and even abnormal psychology of vital statisticians and morphologic pathologists impels them to wrangle largely about artifact-like problems, for the sake of the peace and complacency of the rest of mankind, let them keep these discussions within their own ranks. Let them not endeavor to disturb the existing order of things, which is the result of steady evolution of knowledge and customs and not to be lightly overturned or even amended.

This complacency alone would impel me to question seriously the grounds of our critic's satisfaction with the existing conditions of cancer statistics. Cancer represents a major scourge of the human race, and the terrible quality of its menace is enhanced by the fact that it is slowly but surely increasing in incidence, and that in spite of world-wide study, it remains an almost completely unsolved entity as to etiology, pathogenesis or reason for existence. It is a disease *sui generis*, so far removed in every single characteristic from every other, that before we can fully understand and conquer it we shall probably be compelled to form new concepts of pathology and even add a new branch to our language. These facts well justify us in considering critically the situation which exists in this very important division of

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

the study of cancer, namely, vital statistics, or the incidence of the disease in the broadest meaning of the term.

Our problems may be conveniently grouped in two major divisions—the first, intrinsic and composed of those difficulties inherent in the cancer itself; and the second, extrinsic and made up of the troubles encountered when dealing with “many men of many minds” and some with hardly any mind at all.

The intrinsic problems, at first sight comparatively few and insignificant, on closer inspection become many and very, very real, for when we define carcinoma as a destructive neoplasm arising from some epithelial structure of the body and eventually responsible for the death of its host, we have only scratched the surface. This may be illustrated by a consideration of a few of the more significant subdivisions of this supposed entity.

First, and apparently most elementary, are the cancers of the skin. Epidermoid or squamous-cell carcinomas, commonly and erroneously called epitheliomas, are presumably the most definite group for reliability of diagnosis; but as the skin is not *per se* a vital organ, death from such a cancer can only occur when by invasion or metastasis a mortal lesion is produced, or when, by infection, sepsis finally claims its victim. Hence, the secondary injury is the significant factor, and becomes the primary element of statistical inquiry. Moreover, diagnosis is not always easy. Granulomatous lesions of blastomycosis, syphilis or tuberculosis may simulate cancer; or a cancer may arise from one of these lesions of the skin and the sharing of exact responsibility becomes badly confused. Some extraneous factor often underlies the origin of the cancer, such as a roentgen-ray burn, occupational dermatosis or other chronic injury. They deserve the most careful recognition. Is mycosis fungoides cancer? Probably not, but sometimes it resembles cancer and the expert is needed to differentiate them. Does cancer of the skin ever arise from multiple focuses, and if so how may its primary site be located? At least two other “kinds” of malignant conditions of the skin are closely related and yet must be separated. I refer to the so-called basal-cell carcinoma, rarely fatal, and the malignant melanoma, practically always fatal. Both are usually referable to a congenital defect in either the hair follicle on the one hand or the pigment bearing structures of the skin on the other, and this defect often escapes detection.

Next let us consider the cancers of the breast. Here surely “he who runs may read” and statistics concerning them must have a high degree of reliability. But even granting these premises there are important problems. I have known of a scirrhus adenocarcinoma of

the breast which required nearly twenty years to bring about death, and a carcinoma simplex in which the whole course was a matter of a few weeks. Surely something beside the usual data is necessary before our knowledge of such growths makes any appreciable advancement. Also, as with cancers of the skin, cancers of the breast must kill by secondary effects and the analysis of these is fully as important as the primary factor. Again, the diagnosis is not always easy. Tuberculosis and, rarely, other granulomas may confuse us, and our conception of the relative significance of so-called benign conditions of the breast, such as adenomas and cystic disease, may have a profound bearing on the handling of such diseases and the control of cancers of this organ. What is Paget's disease of the breast, and what factor, if any, is largely responsible for its existence? Did the primary cancer of the breast start as a lump or as a bloody discharge from the nipple? Was a definite injury a preceding event or what trauma incident to child nursing did the breast suffer?

I might similarly consider the malignant polyps of the stomach and colon, the so-called round-cell or carcinoid tumors of the appendix and ileum, the sarcomatous or carcinomatous teratoma of the testis, the epithelial derived tumors of the brain, the branchiogenic cancers, and the peculiar malignant changes to which the ovary and uterus are subject. But I have said enough to remind you that in every portion of the body the diagnosis of a cancer may be bristling with questions which are often difficult or even impossible of solution at this time.

Another phase of our intrinsic problem has to do with the location of the primary growth. This ordinarily simple matter may be of extraordinary difficulty. For example, an extensive so-called cancer of the pleura usually has its primary or mother growth concealed in the lung or even in the stomach or other distant site. In fact according to my pathologic gospel there is no such growth as a primary cancer of the pleura, and yet such a diagnosis is frequently made. An original cancer of the liver is among the rarest of all tumors, but quite commonly the metastasis in the liver completely overshadows every possible source of its origin. In fact, it is quite possible that the parent tumor may become so inhibited in its development as to be extremely difficult to locate; authentic cases are on record in which it may have completely disappeared.

As to duration, our difficulties become even more extreme. To the morphologic pathologist, accidentally discovered cancers are of common occurrence. They may certainly exist for long periods without producing a single ascertainable alteration in the well-being of the individual. We know too little about the inhibitory forces of the

body which hold in abeyance, perhaps for many years, a cancerous growth. The "history" begins with the appearance of this growth above the surface of clinical phenomena, after which its course may be extremely rapid. Like the iceberg, however, a large portion of its "duration" may have been submerged in a symptomless sea. Even the proper evaluation of symptoms has its inherent grief. When does a long story of gastric ulcer or simple indigestion become the short finale of a gastric cancer? When have the irregularities of the menopause given place to the disturbances of a uterine neoplasm? At what time did the prostate gland cease to cause obstruction by benign hypertrophy and begin a similar obstruction because of a malignant transformation? Probably no single element of our statistical data is so full of inaccuracies as that of duration.

It is in the consideration of the extrinsic group of our problems that we may become vituperatively eloquent, for here we are dealing with the mental foibles of our fellow man and his many sins of omission and commission. Psychologically speaking, human nature finds it very easy to discuss and cuss its neighbor's faults and I must admit that for the statistician, particularly one who deals with mortality returns, this same neighbor all too frequently lays himself wide open to a justly deserved scolding. Of all the inane stupidities which man may commit, the physician who fills out a death certificate is often the perpetrator of the lion's share. Not only is he unable to write the English language, but he cannot even read it or understand what he reads. His errors are Gargantuan and he makes so scrambled a mess of the simplest questionnaire that the patience of Job and the serenity of a philosopher must be the essential mental equipment of all mortality statisticians, else their spleen would perforce topple reason from its throne and turn them into raving madmen.

Having eased the pressure somewhat by letting off steam, we may more calmly approach this exceedingly human side of our problems. Our dilemma has to do with the physician, and he often fails us because he does not realize fully what we want, or why; and he does not know the real answer to our question, and knowing that he does not know becomes purposely careless in giving the best possible substitute. On whose shoulders rests the responsibility for this lamentable state of affairs? Does not a certain share belong to the official and semi-official groups which you and I represent? Who ever heard of a medical student being specifically instructed, as a part of his course, how to fill out a death certificate? * What means of intelligent or sympa-

* I have recently learned that in the Minnesota State Department of Health this instruction is now being given. Perhaps in other states this is also true.

thetic propaganda have been adopted to acquaint the practicing physician with the value of properly collected vital statistics, with the aims of this division of the state department of health and the U. S. Bureau of the Census, and with the problems which they are so valiantly endeavoring to solve? To this same physician a governmental bureau is largely impersonal and for impersonal things he has little time or attention. What attempts are made to vitalize the dry dust of the mechanics of vital statistics and to bring before the mind of every physician in the land the imagination gripping epic of our tables of life and death?

We may seem to have drifted from the field of cancer to that of generalities, yet *these* are the problems of cancer statistics and they are major problems. We must, above all, have the intelligent coöperation of the attending physician, and to obtain this we must see that he is both coöperative and intelligent. The problem begins in the medical school and continues throughout the life of the practitioner. He must know what we know about cancer or at least how he can find out what we know. He must be encouraged to classify carefully the character of the malignant growths which kill his patients and to trace their origins and their effects. Beyond all he must be admitted as a partner into this vast undertaking and as such made a full participating member of the firm, with a full knowledge of constitution, by-laws and all rights, privileges and duties thereunto appertaining.

Perhaps our death certificates should be changed to meet the special needs of cancer cases. I am inclined to think so, but with such moves we must proceed cautiously, and it is not my purpose at this time to comment on this important phase of our work. Our main effort must be directed toward the collection of accurate and dependable data concerning deaths from cancer, and to do this we must ourselves advance with the advancement of medical knowledge and encourage the practicing physician, who is the source of these data, to keep pace and to enter into our labors as an intelligent co-partner with full freedom of criticism or suggestion. To accomplish this we must magnify, if possible, the importance of our work. We must never forget nor let the scientific world forget that the field of vital statistics in the study of cancer, as well as of all other diseases, is a vital component of medical research. Statisticians and pathologists are likely to develop an inferiority complex. Laboring in the zone of the interior far from the battle line where the spectacular fighting of disease occupies the world's attention we are tempted by sheer isolation to minimize the basic importance of our endeavors and to fail to plead unceasingly, day in and day out, their significance.

Our problems are, then, like those of all other groups, partly inherent, and as such, for the time being, often without proper solution. They are also partly extrinsic, and as such have to deal with the eccentricities of the human mind and its mode of thought. For all of these there is a large promise of the future ironing out. The stimulation afforded by our efforts and the huge stake created by the welfare of the human race, carry with them an adequate reward for even the humblest of workers in this vast undertaking in which we are privileged to be active participants.

Trembles, or 'Milk Sickness,' Reported Rare Among Humans

"TREMBLES" is the name now given to a disease often called "milk sickness" in the days when population was spreading westward in the Ohio Valley. The disease affects animals as well as human beings, and it may be transmitted to people by animals that have eaten white snakeroot, a poisonous weed. In some areas of Arizona and New Mexico the same disease results when cattle eat either of two species of the rayless goldenrod. Investigators of the United States Department of Agriculture have made feeding experiments with the plants, and J. F. Couch, a chemist of the Bureau of Animal Industry of the Department specializing in the causes of livestock poisoning, has isolated from the plants the poisonous substance, tremetol, which causes the disease.

In pioneer days the disease was reported frequently, usually by the name of "milk sickness." The Department of Agriculture considers "trembles" the better name, as it suggests one of the symptoms. There is no recorded case of the disease in a city. All known cases have originated either on farms or from milk products supplied directly from farms. In the general milk or cream supply for a city or in creamery butter the poisonous substance would be so greatly diluted that it would hardly be possible for it to be harmful, the men who have studied the disease believe.

Eradication of white snakeroot in the trembles areas in the eastern States and of the rayless goldenrods in the Southwest will remove all danger, and neither weed is particularly persistent or hard to eradicate. The bulletin should serve, the author believes, to allay suspicion of milk as a food. Trembles is relatively a rare disease among humans in these days.—*United States Daily*, Jan. 8, 1930.

Free Clinics for the Preschool Child*

SHIRLEY W. WYNNE, M. D., DR. P. H., F. A. P. H. A.

Commissioner of Health, New York, N. Y.

THE duty of protecting the public health is the particular business of governmental or official health agencies. The character of the health protection rendered, while it rests to a certain degree with the citizens of the community, rests to a larger extent with the officials charged with such duties. It is the duty of official agencies not only to exercise police authority for the protection of the public welfare in general but, where they are not otherwise provided, to establish and conduct medical and educational services which the poor require.

In that sense, it is the duty of health departments to maintain clinics for the individual who is economically unable to go to the private doctor, and health departments are justified in maintaining free mental, dental, postural and nutritional clinics for the preschool child if the community fails to give such service through other channels, for among children of this age, malnutrition and defects of teeth, tonsils, and breathing are more prevalent than among school children, to say nothing of the recognized importance of mental hygiene in this early age group.

Let me recall what steps were taken in the campaign against tuberculosis and the venereal diseases. In New York City in the 90's there were practically no clinics available for the diagnosis, treatment and supervision of cases of tuberculosis. The Department of Health not only felt justified but recognized its responsibility to establish special tuberculosis clinics. In the 35 years which have passed, the attitude of public hospitals and clinics toward tuberculosis has materially changed and there are now sufficient facilities in these to take care of the tuberculous. Such patients can now secure the examination, treatment and supervision which the special Department of Health clinics aimed to give. Because this work has been effectively taken over by these other health agencies, the Department of Health is now withdrawing from the tuberculosis clinic field, and in place of the treatment clinics there are being established a few special diagnostic stations to which private physicians can send patients. This same de-

* Read before the American Child Health Association and the Child Hygiene Section of the American Public Health Association at the 35th Annual Meeting, at Minneapolis, Minn., October 3, 1929.

velopment will probably repeat itself in the case of the venereal disease clinics.

When it comes to clinics offering medical examinations, nutritional, dental and mental hygiene services to the child of preschool and school age, you find conditions similar to those existing in respect to tuberculosis 35 years ago. The general hospitals and their out-patient departments have not yet become educated to caring for apparently well children with a view to keeping them well. They do not yet realize the important service they can render in the matter of periodic health examinations. They are still concerned largely with attempting to cure sick individuals. Experience shows that it is far more important to keep persons well than to attempt to cure them after they have become ill. Until such time as we can get the hospitals to adopt this modern viewpoint, it will be necessary for the Department of Health to establish clinics and health stations of the type mentioned.

It has been estimated that 50 per cent—and this is probably a low estimate—of the people in the City of New York can afford to purchase their own preventive health service. The doctor should supply the preventive service to those who can pay—the health department or some other official or semi-public agency to those who cannot.

America is doing more for the expectant mother and the newborn infant than is any continental country; but it is time we concentrated as much energy and activity on the preschool child as we now do on the infant and the school child.

The brightest page in medical and social history is the record of improvement in infant welfare, to which the greatly reduced mortality and improved physique of present-day babies bear eloquent witness. From Sir Arthur Newsholme, former principal medical officer of England's Local Government Board, comes this pertinent quotation:

Knowledge has spread to an extent which puts the poorest mother of today in a better position to secure her infant's health than were the well-to-do a generation ago.

Nor has the school child been ignored in the public health program of an enlightened and progressive community. The same, however, cannot be said for the preschool child. Its health needs have been ministered to in a more or less desultory fashion. There are many private organizations throughout the country interesting themselves in the preschool child, but many of these are not so well equipped as the health departments to direct this vital work most effectively.

The very fact that in New York City approximately 38 per cent of

these youngsters entering school for the first time show some form of physical defect is the best proof possible that we have failed to follow up our health activity with the same thoroughness and effectiveness that we expended on them as babies. Of the total number of children examined last February upon their entrance to school, 25 per cent had defective teeth, 16 per cent had enlarged or diseased tonsils, 14 per cent were undernourished, 13 per cent suffered from defective nasal breathing, 10 per cent had defective vision, over 1 per cent had some form of heart disease, while another 1 per cent had defective hearing, orthopedic or nervous defects. We have found that many school children who are not promoted are not necessarily dull pupils. Usually such boys and girls are suffering from some physical defect that should, and could, have been corrected in their preschool days. When these defects are cleared up, experience shows that these children rank equally with others in scholarship.

It is interesting to note that as far back as 1914, England awoke to the realization that the preschool child was not receiving its measure of health attention. In a letter to county councils and sanitary authorities July 30, 1914, the Local Government Board pointed out:

Up to the present, local authorities in their infant welfare work have concerned themselves more especially with the child in its first year of life; the matter is, however, one which needs to be dealt with on a more comprehensive basis and it is clearly desirable that there should be continuity in dealing with the whole period from before birth until the time when the child is entered upon a school register . . . Extension of the existing work is accordingly needed in two directions: on the one hand it is necessary that measures should be taken for securing improved antenatal and natal conditions; and on the other, provision should be made for continuing the work in relation to children beyond the first year of life.

What the future health of the child is to be depends on the care it has in the beginning, but it also most certainly depends on an effective follow-up of that beginning. Assuredly, a little child is entitled to as much care as a slip of a plant requires in order to take root and live. Yet many children, once they have passed the baby stage, have been given far less care. Many of them, like Topsy, have "just grewed."

The health department is the logical agency to take the situation in hand and lead the way in the matter of providing mental, dental, postural and nutritional services for preschool children. If the fees of the private physicians and dentists specializing in these phases of medicine are not within the reasonable possibilities of the average income, and if the hospitals and other health agencies in the community do not offer help in this direction, the health department must. I believe the health department is justified in maintaining such free clinics to the extent that the health of these children is bettered and safe-

guarded: is justified in leading the way and in carrying on such services until private physicians and other health agencies indicate they are ready and willing to take over this work. I further believe that even when that work is taken over, the health department should still retain a certain amount of jurisdiction.

The time is not far off when every large city will have district health centers at strategic points, just as we have today our district police and fire headquarters. The people of a community would soon protest vehemently if their particular district were not supplied with adequate police and fire protection. There is just as much need in a district for health protection—and it is to the district health center of the future that we look for that protection. The health center will serve those who are too poor to pay the private doctor; it will have a special division catering to the needs of the preschool child; and it will also provide the physicians of the neighborhood with a central service where X-ray facilities and every means of biological analysis will be at their disposal. The doctor is the most important factor in the whole public health movement, and I cannot be too emphatic in my statement that the development of these neighborhood centers should, and would, in no wise interfere with the relationship of the patient to his private physician.

Whenever we mention the maintenance of free clinics—whether for baby, preschool child, school child or adult—we tread on delicate ground. We touch the economic sore spot of the medical profession. The past two decades have witnessed an astonishing amount of curative work by health departments, and the relationship of the private practitioner to the public health program has subsequently become a matter of great contention. Many doctors have displayed hostility from time to time to certain health department activities, on the economic ground that such activities were trespassing on the private domain of the medical profession.

In New York—and I believe it is true of most communities in our country—such activities have rarely been established where the private physician could and would supply the necessary service. Our experience indicates that if, side by side with the establishment of such activities, an honest effort is made to have as much of this work done by private physicians as possible, in a short time the medical profession will realize that, far from making inroads on the practice of the private physician, it will result in a considerable increase in his private practice. After all, most people who can afford to pay a modest office fee prefer to have their children examined and treated by their family physician rather than seek such examination and treat-

ment at a public clinic. It is necessary, however, for the medical profession to be educated to the type of service demanded, and this educational movement is a direct responsibility of the health leaders of the community.

In this connection, let me emphasize the importance of standardizing fees for certain specific services such as the medical examinations of the child of preschool and school age, the periodic medical examination of adults, removal of tonsils and adenoids, toxin-antitoxin treatments against diphtheria, etc. This can usually be brought about through the coöperation of the health department and the county medical society. We have just had an interesting example of such an experiment in New York in connection with the fixing of a flat fee of \$6.00 for the three toxin-antitoxin treatments.

To get back to the specific case of the preschool child whose health wants have been neglected, it is the health department that must get busy along this line. We have concentrated too little attention on those from 2 to 5 years of age, particularly in regard to the mental, dental, postural and nutritional aspects.

I would like to see mental hygiene an important function of the health department. The number of mental defectives, of neuropathic and psychopathic persons in our communities, has increased. If we had the facilities to do preventive work with the preschool child—if we maintained free clinics for mental hygiene where children inclining toward peculiar behavior could be studied—we would be given the wonderful opportunity to adjust them to their environment, and eventually to start them out toward adulthood, unhandicapped by mental illness.

The promotion of mental health belongs with the health department and should be undertaken and maintained by that department. In large cities where there are special institutions for the care of mental cases, it would be advisable for the health department to coöperate with them in the establishment of the clinic facilities demanded.

More intensive nutritional work needs to be done. Only by the adoption of an individualistic method, however, can full benefit accrue from any nutritional service, and that is the type the health department should establish. This is equally true of a postural clinic for the preschool child. The popular "slouch" of today gives every indication that there is a crying need for such service at that early age when good posture can most effectively be taught.

And now we come to the last of the clinics in question—the dental. While New York can boast of 152 dental clinics, maintained by the Department of Health, hospitals and private agencies, and while only

12 of these exclude children entirely, a mere handful treat the preschool child. I am told that two day nurseries give dental service to their children twice a year. Here again we find too little attention given to the preschool period—especially when we realize that the 2-year old child is not too young for his first visit to the dentist.

The New York City Department of Health has only one special preschool clinic. Even this was established through the aid of the Milbank Fund. It is operating in the Bellevue-Yorkville Demonstration Area and reached 414 children during the past year. In coöperation with a number of private agencies, some additional work for preschool children was done. The subject of the examination of more preschool children has been much discussed during the year, and parent-teacher associations and others have been invited to coöperate in teaching parents to have their children of preschool age examined, and defects corrected.

It is my hope that our one special preschool clinic will multiply into as many as are needed to give proper supervision to the little ones who have graduated from babyhood, and yet who are not quite ready for the first step into that more grown-up world of school.

Child care must fail unless the individual mother and the individual child are dealt with as individuals. You can cast bullets in a mould, but children cannot be handled that way. No book can teach the lessons of how to make a child thrive. It is to the private physician the mother must turn for help and advice. But where a mother cannot afford to go to a private physician, the health department is justified in stepping in and offering her help and advice.

Public Health in Mexico

SEÑOR Ortiz Rubio, inaugurated on February 5 as President of Mexico, stated his policies on public health as follows:

In the realm of health and culture my government will use all its power to assure the internal growth of our people by attacking the causes of our infant mortality, which at present reaches almost 50 per cent of births, by developing hygiene in our town and among our workers, especially in the industrial centers.

President Rubio in announcing his cabinet announces the appointment of Dr. Rafael Silva as Chief of the Department of Public Health.

Effect of Prenatal Care Upon the Infant*

CLIFFORD G. GRULEE, M. D.

*Department of Pediatrics at Rush Medical College,
University of Chicago, Chicago, Ill.*

IT is perfectly obvious that the primary function of prenatal care is, and must always be, directed toward the care of the mother; her health is the thing of first importance. It has been felt that such care would have a very beneficial effect upon the offspring. When we assume that the health of the mother presupposes the health of her unborn child, we are taking a position which is probably correct in part, but not definitely proved. We have some reason to raise this question because we know that unfortunately there are born to women, who are apparently in perfect health, deformed and deficient infants. One need only mention mongolian idiocy.

The question of the effect of prenatal care on the infant should be approached from two angles: first, the main, and second, the remote effect. Knowledge of the physiologic and pathologic conditions of the fetus is almost altogether lacking, and with this lack in our knowledge we grope along, empirically attempting to use such scientific facts as we possess. The first test of prenatal care will probably be its effect on neonatal mortality. In spite of the fact that much of the mortality in the first few days of life depends upon obstetrical care, it seems not unfair to expect that prenatal care will bring about a reduction.

The most enlightening statistics from this country are those of Holt and Babbitt. Their first statement calls attention to the imperative necessity of the study of disease in the first few days. They state that of 100 infants' deaths occurring in the first year, approximately 33 are in the first month, 28 in the first two weeks, 22 in the first week, and 13 on the first day. This study was made on a total of 10,000 births at the Sloane Hospital for Women in New York. Of these, 253 were abortions, 429 stillbirths, and 9,318 living.

An analysis of various other statistics shows that the vast bulk of

* Read before the joint session of the American Child Health Association and the Child Hygiene Section of the American Public Health Association, at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

deaths at this age occurs as a result of prematurity or congenital debility. For instance, in the Baudelocque Clinic from 1901 to 1908 there were 345 deaths in the first 10 days of life. Of these, 275 were due to congenital debility (prematurity), 32 to syphilis, 10 to hemorrhage, 5 to digestive troubles, 6 to pulmonary troubles, 4 to icterus and 3 to erysipelas. This group represents a fair list of conditions met with sufficient frequency to claim our immediate attention.

When we analyze the cause of congenital debility, we find that the chief item consists of "unknown causes" 60 per cent, and that twins and triplets account for 15 per cent more, which means that in the present state of our knowledge 75 per cent of the cases of congenital debility are from unknown causes or from conditions over which we have no control.

If we further analyze the remaining 25 per cent, we find that 8 per cent, or about one-third, are due to disease of the mother, of which tuberculosis is most prominent, and such conditions as anemia, nephritis and heart disease are worthy of mention. It would seem that the only way to overcome mortality from these sources in most cases would be to prevent conception.

The next group, consisting of 4 per cent, does not offer much better chance, since it is caused by habitual premature labor. We see, therefore, that almost exactly seven-eighths of our cases of congenital debility are from causes which, in the present state of our knowledge, are beyond our control. The two chief causes in the remaining groups are gynecological conditions, such as placenta previa, and syphilis. We here come to conditions which should be, and are, relatively easy to master and it is in one of these, syphilis, that we get the best results from prenatal care. Acute infections of the mother, eclampsia, trauma and induction of labor, are conditions in which we may at least hope to get better results.

When we turn from the premature to the deaths in infants at term, the picture is decidedly brighter. There is no question that prenatal care has materially reduced the chance of death from syphilis in offspring. The earlier in pregnancy the mother applies for prenatal care, the greater are the chances of success. It may be said that we cannot expect, in the present state of our knowledge, to reduce the deaths from congenital malformation. The other conditions, hemorrhage, digestive and pulmonary troubles and icterus, can be little influenced by prenatal care.

Is the chance of success in reducing infant mortality by prenatal care quite as small as would seem to be indicated by the foregoing analysis? I think not.

There are some outside factors which a simple analysis of statistics from obstetrical clinics do not bring out. First and foremost, prenatal care means, in all probability, better obstetrics. The man who follows his patient through the period of pregnancy is much more likely to prepare himself to meet the problems of confinement more intelligently. Again, it seems altogether likely that our efforts to promote the health of the mother will meet with some unexpected successes for which we cannot account at the present time. And last but by no means least important, such care will stimulate scientific effort to investigate the problems relative to the newly-born infant and the fetus.

In conclusion, I might beg you to withhold your judgment regarding the effect of prenatal care for a period of years. The problems to be solved are neither so obvious nor so easy as those we have had to meet in reducing infant mortality, and success can be expected only after long years of earnest and persistent study.

Effect of Intranatal Care Upon the Infant*

WALTER R. RAMSEY, M. D.

Associate Professor of Pediatrics, University of Minnesota, St. Paul, Minn.

WHAT happens to the child as a result of the obstetrical care it receives during the process of being born? If all prospective mothers were normal, and nature did her job 100 per cent, no intranatal care would be necessary. Neither of these suppositions being true, a certain percentage of cases must have some interference.

It has generally been taught that 80 per cent of all pregnancies are normal and capable of spontaneous delivery. We will assume then that 20 per cent of infants need intranatal care in some degree. In Europe fully 85 per cent of the children are born with no other supervision than midwives who have had more or less training in the field of obstetrics. When interference in promoting the child's delivery is thought to be necessary, an obstetrician is called in. In the 85 per cent supervised by midwives, very little intranatal care is given the child—nature is permitted to take its course and rarely is an anesthetic given the mother.

* Read before the joint session of the American Child Health Association and the Child Hygiene Section of the American Public Health Association, at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

In this country, on the other hand, 85 per cent of births are in the hands of physicians, with a much greater percentage in which obstetrical interference is thought to be necessary. There is no accurate means at present of determining what effect this has upon the infant, and how the number of birth injuries in Europe compares with the number in this country, although the Scandinavian countries with a system of well trained midwives claim the lowest mortality of any in the world.

That there is a large number of injuries to the infant directly attributable to the process of being born, pediatricians, and especially those who have intimate contact with a children's hospital, can attest. Every day and every week during the year there is a constant procession of these maimed children with all varieties and degrees of injuries passing through, for most of which little if anything can be done.

We are constantly seeing the effects of injuries about the face and head as a result of forceps; paralysis of the arms from injured brachial plexus; and fractured femurs from traction. Many of these are transient in character, but not infrequently permanent scars and paralysis of the muscles are carried through life.

The birth paralyses are so frequent and so appallingly hopeless in the way of treatment that one wonders if all of these injuries are inevitable. Of course we know that many intracranial hemorrhages occur in spontaneous births which have had no intranatal care whatsoever. There are, however, a good many of these cases which after instrumental delivery, and after version, give definite evidence of intracranial hemorrhage directly at birth.

The demand in this country for painless, rapid childbirth is responsible for much unnecessary interference on the part of the physician, accompanied by the use of the various forms of anesthetics and drugs. What do we know of their effect upon the infant? If the injuries sustained by the child in the process of being born are inevitable, and the best intranatal care which science can offer—and only when it is needed—is being given, then we must be content. If, however, the conviction which many careful scientific observers have is true, that a good percentage of these tragedies are unnecessary, it is the duty of the American Child Health Association and all others who are interested to make a searching examination to discover the truth and find means to remedy whatever practices are found to be detrimental to the best interests of mother and child.

Effect of Antepartum Care of the Mother*

BLANCHE M. HAINES, M. D., F. A. P. H. A.

Children's Bureau, U. S. Department of Labor, Washington, D. C.

THE specific measures that have effected the reduction of both maternal and infant mortality can best be evaluated by a brief analysis of statistics for a series of years covering causes of infant and maternal mortality together with a consideration of factors affecting the rates.

The latest complete statistics available from the U. S. Bureau of the Census for the entire birth and death registration area are for 1927.

We shall begin our analysis and comparisons of maternal and infant mortality with 1922 and continue through 1927. Late in 1921 Congress passed the Maternity and Infancy Act, which granted federal aid to the states for the promotion of the welfare and hygiene of maternity and infancy. Many states accepted the aid in 1922, and expanding programs as well as new state bureaus and divisions of maternity and infancy were made possible. By the close of 1927 all but 3 states had accepted the terms of the Act. These 3 increased their appropriations and activities in the field of maternal and infant hygiene.

Practically every state-wide public health program relating to maternal care has been initiated since the passage of the Maternity and Infancy Act.

The public, and especially expectant mothers, have been informed of the importance of early and continuous supervision of pregnant women by competent physicians or obstetricians. This information has been given through literature, conferences, visits of public health nurses and the distribution of prenatal letters. Each year state reports show that increasing numbers of childbearing women have been reached.

The birth registration area of 1922 contained 30 states and the District of Columbia. Before the close of 1927 the area had increased to 40 states and the District of Columbia, by the addition of 11 new states (South Carolina was dropped in 1925), 7 of which had higher

* Read before the joint session of the American Child Health Association and the Child Hygiene Section of the American Public Health Association, at the Fifty-eighth Annual Meeting in Minneapolis, Minn., October 2, 1929.

maternal mortality rates and 5 higher infant mortality rates in 1927 than the area as a whole. The inclusion of these states tended to increase rather than decrease the maternal and infant mortality rates in the expanding area, yet both were lower for the whole area in 1927 than in 1922, 76 babies dying under 1 year of age of every 1,000 live births in 1922 and 65 in 1927. The rate for women dying from puerperal causes was 66 for every 10,000 live births in 1922 and 65 in 1927.

A comparison of rates for the states and the District of Columbia in the area in 1922 with those for the same states and the District in 1927, exclusive of South Carolina, gives a fairer picture of conditions and shows a greater decrease in mortality for both mothers and infants. For this area the infant mortality rate was 76 in 1922 and 64 in 1927. The maternal mortality rate was 65 per 10,000 live births in 1922 and 62 in 1927.

Infant mortality showed reductions from all causes in 1927 compared with 1922, except deaths from external causes, for which the rate remained the same in both years. The efficiency of public health measures, including the stressing of breast feeding, better formula feeding, better care and hygiene of infants, and the increase in the number of pediatricians and specialists on infant feeding, were reflected in the reduction of the infant mortality rate due to gastrointestinal diseases from 13 in 1922 to 8 in 1927, and of that due to respiratory diseases from 14 in 1922 to 10 in 1927. The reduction in infant mortality due to natal and prenatal causes from 36 in 1922 to 34 in 1927 cannot be attributed to the better care of the baby after birth, but indicates better care of the mother before the birth. Not only was the infant mortality rate from natal and prenatal causes lower in 1927 than in 1922; there was during the intervening period a downward trend in the rate due to these causes, which seems to reflect the growth of public health work in maternal care.

An analysis of maternal mortality by causes shows slightly lower rates in 1927 than 1922 for accidents of pregnancy and of labor. The decrease in the death rate from puerperal causes is accounted for almost entirely by a decrease in the rate due to albuminuria and convulsions—18 per 10,000 live births in 1922, and 15 in 1927. It is in this group of causes of death that we should expect antepartum care to have the greatest influence. Certainly, the reduction in rate has been coincident with the increase in health instruction to expectant mothers and the improved care given by physicians.

However, we have not yet reached the irreducible minimum for puerperal mortality due to albuminuria and convulsions. This is

shown by the study of maternal mortality for 1927 and 1928 made by 15 states in coöperation with the U. S. Children's Bureau. An analysis of the material for 1927 shows for 13 states nearly 800 deaths due to albuminuria and convulsions. Reports on prenatal care were secured for 728 cases. More than half of the women (373) received no prenatal attention. Of the 355 who had prenatal care, only 20 mothers had the grade of care which conforms approximately to the requirements in *Standards of Prenatal Care* prepared by the Consulting Obstetrical Committee of the U. S. Children's Bureau and issued by the bureau. Seventy-six mothers received care below this high standard, but regarded as good, and 64 had fair care beginning somewhat late in pregnancy. In 3 cases the care could not be graded, but such as was given the remaining 192 mothers in this group was wholly inadequate.

This statement of the amount and kind of prenatal care given relates only to a group of women who died from albuminuria and convulsions; a survey of mothers surviving childbirth might show a larger proportion receiving proper prenatal care.

However, the mortality study shows that of the 728 women in this group for whom a clear report on antepartum care was given, more than four-fifths had inadequate or none.

A further analysis by causes shows no improvement in the rate from puerperal septicemia from 1922 to 1927 in the birth registration area of 1922 (exclusive of South Carolina). The rates were 23.7 in 1922 and 23.9 in 1927 per 10,000 live births.

Of the 3,234 puerperal deaths in 13 states analyzed for the maternal mortality study of 1927, 1,278 (40 per cent) were due to septicemia. One of the objects of the study has been to determine the underlying causes of the deaths from sepsis, which form so large an element of the puerperal losses. Abortions preceded 45 per cent of the deaths. Of 570 abortions, 309 were induced, 154 were spontaneous, 19 therapeutic; for 88 the type was unknown. Thus abortions known to be induced were responsible for about one-fourth of the deaths from sepsis.

A study of 796 cases in the sepsis group to which prenatal care could have been applied and on which a report was made, showed that nine-tenths of the women had inadequate or no care.

Since puerperal septicemia is developed postpartum in a majority of cases, antepartum care is not so influential a factor as when related to toxemia. Such care is advantageous, however, in that earlier recognition of conditions gives the obstetrician a greater choice of methods to be used at the time of delivery. Unquestionably the

elimination of induced abortions would lower the maternal mortality due to septicemia. Information on the relation of sepsis and induced abortion to our high maternal mortality rates should be included in education of the public as to the importance of prenatal care.

CONCLUSIONS

1. Antepartum care of the mother has reduced infant mortality due to natal and prenatal causes and can reduce it still further.

2. The reduction in maternal mortality noted has been chiefly due to a decrease in deaths from albuminuria and convulsions, and antepartum care of the mother has been an important factor in that reduction; further, the extension of adequate antepartum care would prevent many deaths from this cause.

3. Although antepartum care of the mother has not diminished the mortality rate from puerperal septicemia, reduction from this cause may be anticipated as a result of a more thorough understanding by the public of the danger of septicemia following induced abortion.

4. The promotion of antepartum care of the mother through public health programs has effected reductions in infant deaths from natal and prenatal causes and resulted in a lower mortality rate for mothers from puerperal albuminuria and convulsions.

Protection of Children and Women Workers in Germany

LABOR inspectors in Germany report a decrease in 1928 in the number of children under the age of 14 employed in part-time work before or after school, as messengers, newsboys, and the like. This decrease is attributed to a changed attitude on the part of parents, coöperation of school teachers in the enforcement of the child labor law, the prevailing unemployment conditions as a result of which employment agencies give the preference to adult applicants for jobs, and better coöperation between inspectors and the child welfare authorities in enforcing the laws. A shortage of apprentices in many industries is noted due to the decline in the birth rate during the World War.

The inspectors report that both employers and workers show an increased interest in the enforcement of the maternity benefit law, which provides a rest for employed women of 6 weeks before and 6 weeks after the birth of a child. There has been a tendency in Germany recently to increase the amount of the benefit more nearly to approximate the wages lost.

A law of 1929 has increased the amount of the maternity benefit to three-fourths of the wages, and in Saxony the Government pays out of State funds the difference between the wages and the maternity benefit. In order to familiarize the women workers with the law in some places, for instance, Saxony, talks are given to the workers and circulars describing the law on maternity protection are distributed.—*Reichsarbeitsblatt*, Berlin, No. 35, 1929, Part III, p. 302.

Health and Safety Survey of 25 Leading Department Stores in New York*

WILLIAM JACOBSON, M. D.

Department of Health, New York, N. Y.

THE modern department store is a veritable exposition. Its display of goods educates the public to their proper use; for person and for home, for healthful city life and for wholesome country life. More and more as time goes by, has it housed its merchandise in beautiful structures, conveniently segregating its articles into groups. Its contact with the public being intimate, its environment and personnel need be such as to protect the health of its shoppers. Its relations with its employees being dependent upon efficiency, it must also insure for them safe and healthful working conditions. The purposes of this survey were to determine the extent the department store succeeded or failed in its responsibilities toward the shopper and toward the worker, and to correct conditions inimical to health and safety.

New York City furnishes such a wealth of material that it was necessary to limit the number of stores for study. Twenty-five have been investigated: 16 in Manhattan, 4 in Brooklyn, 4 in the Bronx, and 1 in Queens. Of these the first 3 (Table I), A, B, C, were from the great chains of 5 and 10 cent stores, and the remaining from the department stores. The size of these stores may approximately be measured by the number of employees in each as shown in Table I.

To give an idea of the tremendous business done, it is worth mentioning that the yearly sales of one store amounted to over 122 millions of dollars.

That the responsibilities of the operations of department stores may be properly placed, it was necessary to become familiar with their organization charts, where available, which vary in arrangement with each store. The general functioning of a store requires financing, merchandising, publicity, service and personnel. There are many subdivisions of these and it was valuable to know them in order to establish properly their relations with the occupations of the personnel.

* This work was carried on under the direction of E. S. Morton, M.D., Chief of the Division of Industrial and Adult Hygiene, Department of Health, New York, N. Y.

"	L	4,101	Queens	Y	120
"	M	754	Total, all Boroughs, all stores		40,965

Though all are workers of a mercantile establishment, the employees were found distributed in the following occupational groups: trade, manufacturing and mechanical industries, transportation, professional services, and personal services. In order to observe the particular kind of work of each employee, the materials handled by him, the possible injurious working conditions, exposures or hazards surrounding his work, and the precautions taken or omitted in overcoming such hazards, the writer visited all the places which housed the various activities.

For the purposes of this survey it has been found convenient to classify the activities into the following general divisions: (1) Buying, (2) Receiving, (3) Marking, (4) Storing and warehousing, (5) Transporting and delivering, (6) Displaying, (7) Selling, (8) Manufacturing and altering, (9) Serving shoppers, (10) Serving employees, (11) Serving building, (12) Administrating finance and statistics. Each of these general divisions comprises numerous special activities occupying spaces in the structure or structures of the plant. The writer has

TABLE II

MERCHANDISE ACTIVITIES

Buying, Receiving, Marking, Storing, Selling

Merchandise office and management
Receiving and marking rooms—Stocking and warehousing rooms
Sample room
Comparison office
Selling departments
Dry goods and accessories
Home furnishings and accessories
Women's and misses' ready to wear and accessories
Infants' and children's wear
Men's and young men's wear
Small wares
Miscellaneous
Service departments

presented in tables, the number of stores engaged in each special activity.

Table II shows the merchandise activities, each store handling various articles too numerous to mention here. In one there were 160 selling departments. From a health point of view it is important to know for example that brushes are free from anthrax, that they have been properly marked for identification, and that cosmetics are free from poisonous ingredients. Similar knowledge is necessary for other goods. Injury to workers' hands from pin tags, slivers, etc., while receiving and marking goods is to be avoided. Crowding of merchandise and congestion of shoppers in various aisles are to be prevented. These are only some of the conditions that were investigated.

TABLE III
DISPLAYING AND PUBLICITY ACTIVITIES

Advertising
Card and sign work
Window dressing
Internal display
Radio broadcasting

Table III shows the displaying activities. Here we found eye strains, posture strains, fatigue from excessive heat in window dressing, advertising and card and sign writing.

TABLE IV
TRANSPORTING AND DELIVERING ACTIVITIES

Activity	Number of Stores (Out of 25) Engaged in Activity
Packing and wrapping	25
Conveying (inside)	22
Routing	19
Sheet writing	19
Drivers parcel delivery	17
Hold merchandise	16
Wrong address	16
Parcel returns	12
Warehouse packing and shipping	12
Express and parcel post	12

Table IV deals with 10 divisions of the transporting and delivery activities. Most of this work is done in basements where often poor light, inadequate ventilation and dust affect the health of the worker. Several young girls exposed to these conditions in one department store contracted tuberculosis while employed in the packing department. It will be seen that every store is not engaged in each activity.

Table V shows the factory and workshop activities. So many of the department stores are engaged in the various manufacturing processes that they have become factories. Fifty-four activities are listed

Soda fountain and luncheon	14

Table VI shows 10 activities involving the handling of food and drink, requiring the examinations of employees as to their freedom from infectious diseases, and the compliance with health regulations relative to the wholesomeness of and the absence of contamination from foods, etc.

TABLE VII

SERVING SHOPPERS' AND SERVING EMPLOYEES' BEAUTIFYING ACTIVITIES

Activity	Number of Stores (Out of 25) Engaged in Activity
Barber shop	11
Beauty shop	12
Manicuring	13
Hair dressing	11

Table VII lists the barber shops, beauty shops, manicuring and hair dressing establishments. These are required to obtain a permit, after approval by the Department of Health.

Table VIII practically consists of the humane work. There are 30 items referable to health and welfare services. Thus out of the 25 stores, 11 employ physicians, 4 engage dentists, and 14 have nurses. Though 9 require medical examinations of their workers upon employment, only 1 fully reexamines them at regular stated periods. In only 2 stores are the physicians giving adequate time to health research, collection and analysis of statistical data, and supervision of environments. There is room for improvement in other humane services.

Store bulletins and magazines	7

Table IX comprises 23 activities relating to the maintenance, equipment and protection of the plants and buildings of department stores. Operated on a large scale some of these may be again considered as those of factories, viz., carpenter shops equipped with motor woodworking machines needing dust controlling devices; painting shops having spraying and other processes requiring protection. The cleaning, ventilating, lighting, heating and power systems require not only engineering skill but special knowledge of health and safety. The need of accident prevention was encountered in observing the

ranging from 18 to 25 years of age, engaged in the processes of receiving the money and slips of purchases from various departments, and returning the change and slips. On entering one of these rooms the writer was reminded of the noises of the old fashioned celebration of Independence Day. These bombardments were caused by the impact of the carriers containing the money and slips as they emerged from

TABLE I

PERCENTAGE OF *B. prodigiosus* IN THE SEGMENTS OF THE GASTROINTESTINAL TRACT 2 HOURS AFTER INGESTION WITH THE RESPECTIVE FOOD VEHICLES

	Fasting	Meat	Meat and Infected Meat Juice	Infected Meat
Stomach	0	10	30	90
Duodenum	0	20	30	60
Jejunum	0	20	50	70
Upper half Jejunum	trace	30	50	80
Lower half				
Ileum	10	70	80	100
Cecum	15	80	90	100

cecum at time intervals after feeding are indicated. It is apparent that the meat diet in some ways inhibits the bacterial destroying power of the upper intestinal tract. The changes that take place within the stomach, duodenum and cecum of dogs fed with plain milk, alkaline milk and *B. Shiga* proteins (to produce diarrhea) are shown in Figures I to V inclusive (see Arnold').

With this brief review of a few of our previously reported experiments as a background, we wish to call attention to the importance of the food vehicle in experimental food poisoning conditions. Without going into detail, we have found it necessary to use the same age group of dogs for comparative experimental work. For the experiments to be reported, young dogs within the 6-10 months old age group were used. Each experiment to be reported represents an average of the results obtained upon 12 dogs. *B. prodigiosus* was given to each animal with the food. The dogs were killed in the ether chamber 2 hours after feeding. The distribution of the test bacteria was determined by taking specimens from the various levels of the gastro-

TABLE II

PERCENTAGE OF *B. prodigiosus* IN THE SEGMENTS OF THE GASTROINTESTINAL TRACT 2 HOURS AFTER INGESTION WITH THE RESPECTIVE FOOD VEHICLES

	Fasting	Bread and Broth	Bread and Infected Meat Juice	Meat alone
Stomach	0	0	0	10
Duodenum	0	0	0	20
Jejunum	0	0	0	20
Upper half Jejunum	trace	20	20	30
Lower half				
Ileum	10	30	20	70
Cecum	15	20	30	80

intestinal tract within 5 minutes after death. In previous reports we have shown that the distribution of *B. enteritidis*, *B. typhosus* and *B. pyocyaneus* is the same as that found for *B. prodigiosus*. The latter organism has been used to simplify the technical procedures.

Table I shows the differences in the distribution of the test micro-organism 2 hours after administration in fasting, meat meal, meat plus enteritidis—infected meat juice (heated 100° C. for 1 hour) and enteritidis—infected meat. Table II shows results obtained when bread moistened with broth is fed. Table III gives a résumé of the results obtained by milk feeding. Figures I, II and III illustrate graphically the contents of the preceding tables.

TABLE III

PERCENTAGE OF *B. prodigiosus* IN THE SEGMENTS OF THE GASTROINTESTINAL TRACT 2 HOURS AFTER INGESTION WITH THE RESPECTIVE FOOD VEHICLES

	Fasting	Milk	Milk and Infected Meat Juice	Infected Milk	Meat alone
Stomach	0	0	0	0	10
Duodenum	0	0	0	0	20
Jejunum	0	trace	10	0	20
Upper half Jejunum					
Lower half Jejunum	trace	10	10	10	30
Ileum	10	20	20	20	70
Cecum	15	20	30	10	80

Even the enteritidis-infected meat did not cause diarrhea. We wish to bring out here that changes in the intra-intestinal bactericidal power are demonstrable following the ingestion of various foods. Meat causes a change in the intra-intestinal endogenous bacterial flora. The duodenum and jejunum contain a bacterial flora similar

to that found in the ileum and cecum. The power to destroy exogenous bacteria is diminished.

The gastrointestinal tract is changed in such a manner after the ingestion of a high protein meal that it is more sensitive to certain irritants than when some other foods are eaten. This report deals with heated enteritidis-infected meat only. The presence of viable *B. enteritidis* has been excluded. It is thought

FIGURE III

that most of the *Salmonella* group responsible for food poisoning outbreaks in man are derived from animal sources.

Milk and milk products should be subjected to such infectious material more than most foods. It is well known that milk is seldom the vehicle of the causative agent of food poisoning. From our experimental results it would seem that the toxic substances present in heated enteritidis meat cultures are not irritants to the gastrointestinal tract when added to milk. We have previously shown¹ that unheated enteritidis-infected milk was not a gastrointestinal irritant in our experimental animals.

The food vehicle in food poisoning outbreaks plays an important rôle. We have called attention to some of the changes that take place in the host that accompanies an increased susceptibility to gastrointestinal irritation.

Division of Maternity and Child Hygiene, Chile

IN order to enlarge the scope of the work with mothers and young children in Chile, in accordance with the social insurance law of 1924, the Ministry of Social Welfare of Child (Ministerio de Previsión Social) issued regulations on November 11, 1929, for the establishment of a Division of Maternity and Child Hygiene (La Sección Maternal y del Niño). This division will centralize the supervision over all maternal and child hygiene agencies, coördinate the work of the agencies receiving Government subsidies, give information to private agencies, and organize health work for the working mother and her child.

The Division is to be in charge of a medical director, a specialist either in obstetrics or in pediatrics, who will be assisted by the previously established Superior Council on Maternal and Infant Welfare. The duties of the director will be:

1. To formulate rules for the work of the maternal and child health agencies
2. To supervise the work of the medical inspectors
3. To study and to suggest the necessary child health measures
4. To introduce uniform statistical methods in the child-caring institutions

The Division of Maternity and Child Hygiene will carry out its work by means of "children's bureaus" (oficinas del niño), one to be established in each of the ten cities which are the seats of the district hospitals. The functions of these bureaus will be to give instruction in prenatal and postnatal care; protection of the mother during pregnancy, confinement, and the nursing period; and aid to expectant mothers and to children.

The staffs of the children's bureaus will consist of pediatricians, obstetricians, and visiting nurses.—*Diario Oficial de la Republica de Chile*, Santiago, Nov. 29, 1929, p. 6611.

Industrial Methyl Chloride Poisoning*

HERMAN M. BAKER, M. D.

Evansville, Ind.

THE growing complexity of modern industry is continually thrusting forward problems in the identification and management of new industrial diseases. With the rapid development of the refrigeration industry there has been brought to our attention a group of hazardous gases. I shall confine myself to a brief discussion of one of these, methyl chloride.

While extensively used in the chemical industries and as a local anesthetic, this gas has received little attention in the literature of industrial hygiene, and even toxicologists have failed to consider it of sufficient importance to require more than passing notice. In 1876, Eulenberg¹ reported the toxic action of this gas. In 1879 a committee on anesthetics of The British Medical Association² investigated it and reported a narcotic action. It was again reported by Kionka³ in 1900. The first cases of industrial poisoning were those of Gerbis,⁴ who in 1914 reported 2 cases. In 1923, Roth⁵ reported a series of cases occurring in industry, and Schwarz in 1923⁶ 10 cases with 1 death. Henderson and Haggard⁷ issued a monograph on poisonous gases and the treatment of such poisonings in 1927, and under the group of "more toxic anesthetics" methyl chloride is described at some length. The writer⁸ reported a series of cases of poisoning occurring in industry in 1927, and recently Kegel, McNally and Pope⁹ report 29 cases of poisoning with methyl chloride in Chicago, of which 10 died. During the early months of 1929 the U. S. Bureau of Mines¹⁰ conducted a series of experiments to determine the toxicity of methyl chloride. Guinea pigs were exposed to vapor concentrations of 41.5 per cent for 8 minutes down to those of 0.07 per cent for 810 minutes. This work is being continued and further data will no doubt be available soon.

I have the permission of Dr. H. M. Kauffman¹¹ of Evansville, Ind., to report 75 cases observed by him from 1926 to 1929. These were all among employees of a refrigerator manufacturing plant. There were no deaths, or severe sequelae.

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

The condition most frequently confused with methyl chloride poisoning in the Chicago cases was food poisoning. It will be borne in mind that nearly all of these cases occurred in small apartments and were caused by leaks in refrigeration systems. In my experience the most frequent mistake was that the condition was called influenza or encephalitis, as there happened to be an epidemic of influenza present at the time most of these cases developed. It should be differentiated from ethyl and methyl alcohol intoxication. In the latter case the difficulty would be great; also poisoning from carbon monoxide, from the heavy metals, and epidemic meningitis.

In view of the Chicago experience it would be well for health authorities and hospital attendants to check the histories of cases admitted with a diagnosis of food poisoning, to learn whether there had been exposure to refrigerant gases. The knowledge that an individual is employed in the refrigeration industry would be of the utmost importance in differential diagnosis.

TREATMENT

The patients should be hospitalized. Alkaline balance should be established. If the patient is unable to swallow, this should be done by administering alkalis by rectal drip or intravenously. In severe cases, oxygen should be administered until the ketonic odor has disappeared from the breath. If there are convulsions or similar nervous manifestations, bromides may be used in large doses. Under no circumstances should chloral or chloroform be used. Special symptoms should be met by appropriate treatment. I found strychnine to be of value in after-treatment, and Dr. Kauffman states that he considers this the most valuable drug he has used. The most important factors in treatment are early recognition of the disease and prompt removal from exposure to the gas.

SEQUELAE

With the exception of one case which developed foot-drop, I saw no permanent damage. Nearly all cases complained of insomnia lasting from several days to three weeks after an attack. Several developed fine tremors which lasted a week or two after all other symptoms had disappeared. Anorexia was very common. Kegel, *et al.*, report severe sequelae in several cases, among them ataxic gait, aphasia, incoördination of legs, disturbances of vision, emotional instability, etc. It will be borne in mind that these were all severe, acute cases which had received, no doubt, massive doses of the gas, while my cases were of the more chronic type.

CONCLUSIONS

Industrial methyl chloride is absorbed through the respiratory tract in amounts sufficient to intoxicate workmen, unless special precautions are taken to guard against this danger.

It is a toxic agent, slowly removed from the body, and therefore becomes cumulative in its action.

It can be detected in the urine as formate.

If it does not cause death it may well produce permanent crippling injury to the various organs and especially the nervous system.

Poisoning by methyl chloride should be thought of in all workers in the refrigeration industry when this gas is used as the refrigerant, and it should be considered in all people coming to physicians or hospitals with any of the above symptoms if there is a possibility of exposure in their homes or in places of occupation.

A NATIONAL MOVEMENT FOR CLEANER CITIES

THERE are three sanitary services which are indispensable to cities and towns as we know them in America today.

The most important and the first to be built is the water supply. Considerations of health and decency require that there shall be an abundant provision of clean, pure water for every house, to say nothing of what is demanded by industry. We have here an engineering undertaking which has been highly developed from the scientific and technical standpoints. The works which are required are customarily built after extensive investigations have been made and plans and estimates carefully prepared. Frequently men who have become recognized for expert ability in this specialty are called upon to act in a consulting capacity, so that there shall be no serious fault with the system after it is actually constructed.

The second indispensable service, and one which is generally introduced soon after the water supply, is sewerage. This is also an engineering undertaking and if it is well designed the question of final disposition of the liquid wastes is provided for. In sewerage we have a service which bears a resemblance to water supply in certain particulars, but in the past it has been too common for a restricted view to be taken of the ultimate necessities in the way of a plan which will adequately meet the requirements of the future, to say nothing of disposal. As a result, cities are frequently compelled to introduce extensive changes in their sewerage arrangements, including main drainage and disposal works, the object of which is to collect to a central point the drainage of the houses and streets and treat it in a way which

will make it possible to discharge the effluent into the natural water courses, without danger or offense.

The third sanitary service comprises the cleaning of the surface of the streets and the collection and disposal of the solid wastes of domestic and industrial origin. We have here a subject which is markedly different from the water supply and sewerage in many particulars. The money invested in the plant is comparatively small and the number of men employed, on the other hand, large. In equipment and methods a great deal is left to the experience and judgment of those who do the work. This service is almost always unpopular with the citizens. It is not too much to say that in nothing done by the municipality is there such an opportunity to waste or save money. The ways in which the garbage and other refuse are collected are often primitive and insanitary in the extreme, and the disposition of them unsatisfactory.

Here is a matter which urgently demands attention. Those who have given it qualified study are of the opinion that if attention is properly focussed upon it and a national movement can be started to improve the cleaning services of our cities and towns, better methods and equipment can be developed which will not only result in greater cleanness but decided economies. Certainly recent European practice warrants this opinion:

At the annual meeting of the American Society of Civil Engineers this matter was discussed by the Sanitary Engineering Division of that association and a proposal was made and favorably acted upon requesting that a committee of the society be created to coöperate with accredited representatives of other interested national organizations to look into the whole subject of municipal cleansing with the purpose of recommending better procedures, apparatus, and cost accounting. This is believed to be the first attempt upon a broad scale to bring system and order to a sanitary service which means so very much to the public health and welfare of our American communities.

STREPTOCOCCI, TONSILS AND RHEUMATISM

THE bacteriologist has no more difficult task than to classify the streptococci. That they are among man's chief enemies no one doubts. It is equally certain that they are widespread and that many different types are found. There are constant attempts to connect some particular streptococcus with a given disease, but practically always just when it seems that something has been proved, other workers show that the evidence will not stand close investigation.

The streptococcus has been incriminated as the cause of rheumatism for a long time, and the tonsils have been suspected as being the chief portal of entry. Based on this belief, tonsillectomy has been recommended and carried out in thousands of cases. There is no question that streptococci can be isolated from the tonsils in practically all cases of rheumatism. Some have believed that the toxic effects are due to the absorption of poison from the tonsils, while others have held that the organism itself gains entrance to the blood stream, which, in a way, seems to be borne out by the occurrence of valvular disease of the heart following rheumatism, and by the growths found in rheumatic joints. Certain observers have produced arthritis and endocarditis in experimental animals by inoculation with streptococci from various sources, some rheumatic and some not, while others have shown that streptococci from non-rheumatic cases produce arthritis often indistinguishable from that due to the so-called streptococcus rheumaticus. There can be little question that streptococci have been found in rheumatism which are identical with those often found in non-rheumatic cases.

In a recent piece of work,¹ 190 strains of streptococci were isolated from 50 cases of rheumatism, and 157 from 48 non-rheumatic. These various strains were carefully compared and identified as far as possible. The most generally accepted classification is hemolytic and non-hemolytic. The percentages of these varieties found in the two classes of cases were almost identical, varying only by hundredths of a per cent. There was a slightly greater difference, though not at all a significant one, between the green and non-green types, and the same may be said of the four other named types identified. Even the number of streptococci per tonsil was very much the same. The very natural conclusion was reached that streptococci from rheumatic tonsils do not vary greatly from those in non-rheumatic cases. Even on Crowe's medium, which is being used in England as a method of classification, it was impossible to differentiate plates made from rheumatic and non-rheumatic cases.

One naturally turns from these findings to the question of removal of the tonsils for the cure and prevention of rheumatism. This has been strongly advocated by many observers, especially by Poynton and Paine, who were among the first to demonstrate what they considered a special coccus in rheumatic tonsils, and to connect it with the disease. From the practical and clinical standpoints there can be little question that removal of enlarged and diseased tonsils benefits most children, and in spite of the uncertainty concerning classification, there is little doubt that repeated or continued low-grade in-

fection of these glands cannot but be injurious. The work under consideration seems to show conclusively that as far as this is concerned, the particular type of streptococcus is not important, but none the less, the authors consider that the removal of the tonsils is "probably a valuable prophylactic and therapeutic measure."

We have in these columns reviewed three volumes devoted entirely to consideration of the streptococci,² which show that classification of these organisms is far from being an accomplished fact. The recent findings in regard to the streptococci supposed to be specific for scarlet fever and rheumatism also demonstrate this.³ Clinicians, pathologists and bacteriologists alike are glad to have any facts which will help them concerning this puzzling problem.

RESPIRATORY DISEASES AND DISABILITY

A REPORT just issued by the U. S. Public Health Service of sickness and non-industrial injuries occurring in some 35 sick benefit associations and company relief departments, 1921-1928 inclusive, emphasizes two points of which all health officers and sanitarians are aware, but the significance of which the public generally does not seem to grasp.

Among every 1,000 men employed, there were annually 103.5 cases of disability which lasted for 8 days or longer. The respiratory diseases were responsible for 42.4 per cent of the total, though even this does not include the full amount. Among this group, influenza or grippe was the most common affection, amounting to 57.5 per cent of the cases in 1928, as against 50 per cent during the entire period studied. The bright spot is the decreasing influence of tuberculosis, which was lower in 1928 than in any of the years studied, a finding which accords with the figures for the general population.

The control of respiratory diseases is the blackest spot in our preventive program. We have made comparatively little headway in controlling the most common of the contagious diseases. One great reason for this is that human conduct is involved—of all the factors involved in the spread of contagion the most difficult to control. In spite of the disfigurement of our public buildings, street cars and other public conveyances by signs against spitting, the American public still continues to expectorate widely, profusely and frequently, in addition

to which comparatively few people cover their noses and mouths when sneezing or coughing. Even physicians and sanitarians are far from being guiltless in this respect.

In many parts of our country, but especially in the North, for 3 to 5 months of the year, respiratory infections are met with daily and hourly. Coughing and sneezing are the order of the day. In spite of the school surveys demonstrating the large part played by common colds in absenteeism both among pupils and teachers, no one has had the courage to advocate removal from classes on account of the common cold. If this were done, classes would frequently be more than decimated. Like the poor, colds and sore throats are always with us, and we have learned to regard them as trivial affections; yet who knows the vast amount of injury which they inflict on the individual and in the aggregate? We recognize their decidedly pernicious influence on certain diseases like tuberculosis, but in ordinary life we pay entirely too little attention to them.

No one knows the cause or causes of the ordinary cold, yet no one has escaped its clutches. All studies as to the cause of colds have been disappointing, misleading or contradictory. In spite of this, the biological houses have put out vaccines of various sorts, mostly of the gunshot prescription type.

In view of our present knowledge, it seems that campaigns against promiscuous coughing and sneezing must continue; that the droplet infection theory of Flügge must be emphasized in our teaching; that we insist upon the avoidance of exposure; and that children be taught at home as well as in the schools the necessity of protecting the mouth and nose when sneezing and coughing are necessary.

A New Journal

WE extend a cordial welcome to *Municipal Sanitation*—a Journal for the Practical Sanitary Official, the first issue of which has just appeared. The title explains its object.

Abel Wolman, who is Chairman of our Committee on Meetings and Publications, and also editor of several other journals, is the Editor. George W. Fuller, President of our Association in 1929, is Chairman of the Advisory Board.

The first number is extremely interesting, containing material of value not only to the readers for whom it is primarily intended, but to all who are interested in municipal sanitation.

The printing and make-up are excellent, and the illustrations good.

We wish for it all success.

ASSOCIATION NEWS

PLANS FOR THE FORT WORTH MEETING

ANNOUNCEMENT is made of the appointment of A. H. Flickwir, M.D., Director of Public Health and Welfare of Fort Worth, as Chairman of the Local Committee for the Fifty-Ninth Annual Meeting. Dr. Flickwir was formerly Health Officer of Houston and has been President of the Texas Association of Sanitarians. He is well known to many members and Fellows of the Association. Although the Local Committee has not yet been completely organized, announcement has been made of the following appointments:

FORT WORTH LOCAL COMMITTEE

A. H. Flickwir, M.D., *General Chairman*
E. D. Hopkins, *Secretary*
John Stanley, *Treasurer*
M. C. Anderson and C. M. Davis, *Finance Committee*

CITIZENS' COMMITTEE

Mayor William Bryce, *Chairman*
M. E. Gilmore, M.D., *Vice-Chairman*
I. C. Chase, M.D., *Vice-Chairman*
J. C. Anderson, M.D., *Honorary Vice-Chairman*

RECEPTION COMMITTEE

Walter B. Scott, *Chairman*
J. C. Anderson, M.D., *Honorary Vice-Chairman*

ENTERTAINMENT COMMITTEE

Truman Terrell, M.D., *Chairman*
D. W. Carlton, *Secretary*

PUBLICITY

G. W. Luckey, M.D., *Chairman*
Roscoe Ady, *Vice-Chairman*

REGISTRATION

Chester Hollis

MEETING ROOMS

L. A. Quigley, *Chairman*

INSPECTION TRIPS

Dudley Lewis, *Chairman*
W. O. Jones, *Secretary*

LADIES' ENTERTAINMENT

Mrs. Henry Trigg

MEMBERSHIP COMMITTEE

H. K. Read, M.D., *Chairman*
E. G. Eggert, *Secretary*

HOTELS

Jack H. Hott, *Chairman*

EXHIBITS

Tom Bond, M.D., *Chairman*
J. W. Ridgway, *Vice-Chairman*

INFORMATION

C. F. Hayes, M.D., *Chairman*

EDUCATIONAL EXHIBITS

Holman Taylor, M.D., *Chairman*
Victor M. Ehlers, *Vice-Chairman*

At the first meeting of the Sub-committee on Annual Meeting Program which was attended by the Chairman of the Local Committee, it was decided to allot to each section two individual sessions and two joint sessions. The committee, expressing the sentiment of many members, recommended that the greatest possible emphasis be placed on joint sessions at Fort Worth. The committee also tentatively approved three general sessions, including the opening general session on Monday evening, a luncheon session for members and Fellows at which the reports of the four standing committees and the Executive Board would be presented, and a session following a banquet. Two topics for joint sessions were recommended: (1) the anti-diphtheria program, and (2) meningitis and undulant fever.

Program regulations following those in force in past years were approved, and it was decided to continue the policy of scheduling papers in accordance with the time-table plan which was begun at the Chicago meeting.

The date of April 1 was designated as the closing date for the first tentative program, and July 1 for the preliminary program. September 15 was designated as the last date for accepting material for the final program.

The Executive Secretary reported conferences with Dr. Villanueva, the Chief of the Federal Health Service of Mexico, in which Dr. Villanueva promised to send to the Fort Worth meeting a delegation of Mexican public health workers.

A tentative list of trips to places of general and scientific interest was approved. This list includes trips to packing plants, sewage disposal and water purification plants, airports, hospitals, health centers and the local health department.

Headquarters for the meeting will be at the Hotel Texas and the majority of the meetings will be held at this hotel, as will also the educational and technical exhibits. Information concerning hotel accommodations in Fort Worth and railroad facilities will be published in a later issue of the JOURNAL.

DATES CHANGED FOR WESTERN BRANCH MEETING

William P. Shepard, M.D., Secretary of the Western Branch of the American Public Health Association, announces that the dates of the special meeting of the Association to be held at Salt Lake City have been changed to June 12 to 14. This will enable the state health officers in the western states to proceed directly to Washington for the Surgeon General's Conference to be held the following week and also for the Conference of State and Provincial Health Authorities.

This will be the first opportunity in several years for many of the western members to attend a meeting of the association, and it will undoubtedly be the most representative public health meeting ever held in that region.

The western aspects of the tuberculosis problem will be covered in papers by Dr. Gerald B. Webb of Colorado Springs and Dr. H. W. Hill of British Columbia. A tentative session has also been scheduled on the public health aspects of the Boulder Dam project. It is believed that this will be the first conference held on this subject.

Further details concerning the program may be obtained from Dr. W. P. Shepard, Assistant Secretary of the American Public Health Association at 600 Stockton St., San Francisco, Calif.

INTERNATIONAL CONGRESSES AT DRESDEN

In connection with the International Hygiene Exhibition to be held in Dresden this summer there will be held a number of notable scientific congresses of interest to public health workers, among which are the following:

- German Municipal Health Officials
- German National Organization for Public Health Education
- German League for Public Health
- German Society for School Hygiene
- German Society for Industrial Hygiene
- German Central Committees for the Control of Tuberculosis and Cancer
- German League for Mental Hygiene

The Executive Council of these congresses has extended an invitation to the American Public Health Association, which invitation has been accepted, to send delegates to these congresses. The delegation will leave New York on June 14, which date will permit attendance also at the meeting of the Royal Sanitary Institute to be held in Margate, England, June 21 to 28, and will return to New York about August 4. Further details of the arrangements will be communicated to the members.

An invitation has also been received from Dr. Calmette for these delegates to visit the Pasteur Institute, and to attend the International Congress of Micro-biology to be held in Paris at the end of July.

AMERICAN PUBLIC HEALTH ASSOCIATION

EXECUTIVE BOARD MEETING

THE Executive Board of the Association met in New York on February 2 with Drs. Bishop, Hassler and Vaughan absent.

Reports of Standing Committees—Reports were received from the Committee on Fellowship and Membership, Committee on Meetings and Publications and Committee on Administrative Practice.

Report of Treasurer—The Treasurer presented the report of the auditor, which showed the situation of the Association as of December 31, 1929, to be as follows:

INCOME, JANUARY 1, 1929, TO DECEMBER 31, 1929

Membership Dues	\$29,684.13
American Journal of Public Health and The Nation's Health	35,400.57
Syndicated Public Health Bulletin	4,489.00
A. P. H. A. Publications (net profit)	4,093.80
Other Publications (net profit)	2,285.67
1929 Annual Meeting Exhibits	15,783.50
Surveys	20,267.15
Consultant Service	1,823.34
Grants:	
Administration—	
Com. on Adm. Prac.	19,581.34
Rural Study	12,473.07
Hospital Study	603.63
Laboratory Study	96.13
Health Conservation Contest	8,220.78
Extension of Registration Area	2,834.71
Chautauqua Health Program	14,071.46
Interest and Discounts	1,403.12

Total General Fund Income

\$173,111.40

EXPENSE, JANUARY 1, 1929, TO DECEMBER 31, 1929

Principal Operating Budget:

Administration	\$22,871.61	
Membership and Promotion	25,807.23	
American Journal of Public Health and The Nation's Health	19,054.44	
Syndicated Public Health Bulletin	4,126.87	
Contingent	2,108.80	
1929 Annual Meeting Expense	6,044.56	
1929 Annual Meeting Exhibits	4,682.01	84,695.52

Committee on Administrative Practice:

Administration	\$19,901.48	
Field Service	17,226.80	
Rural Study	12,473.07	
Hospital Study	603.63	
Laboratory Study	96.13	
Health Conservation Contest	8,220.78	58,521.89

Chautauqua Health Program	14,071.46
Committee on Registration Area	2,834.71

Total General Fund Expenses	\$160,123.58
Plus Reserve for Uncollectible Accounts Receivable	550.03

Net General Fund Expenses \$160,673.61

ASSETS—GENERAL FUND

Cash	\$24,060.43
Accounts Receivable	5,555.65
Investment Securities	18,083.25
Inventories:	
Sundry Publications	3,458.11
Office Equipment	1,869.02
Rural Study Equipment	756.15
Deferred Expense	1,884.63

Total General Fund Assets \$55,667.24

LIABILITIES—GENERAL FUND

Accounts Payable	\$5,923.79	
Accounts Receivable—

Fund		2,172.14
Net Asset Value Life Member-		
ship Fund		2,063.89
Total Net Asset Value as of De-		
cember 31, 1929		\$23,102.67

The Executive Secretary presented estimates of income for 1930 and the budget was approved as follows:

General Administra-	
tion	\$44,196.00
Committee on Fellow-	
ship and Member-	
ship	13,056.00
Committee on Meet-	
ings and Publications	58,760.00
Committee on Admin-	
istrative Practice	90,480.00
Committee on Re-	
search and Standards	5,000.00
Total	\$211,492.00

West Coast Branch—At the recommendation of the Executive Secretary the Board approved the appointment of William P. Shepard, M.D., as Assistant

Secretary of the American Public Health Association at a salary of \$1.00 per annum, to be stationed on the west coast. A first appropriation of \$400 was made for the purposes of this office.

Committee and Other Appointments—The following appointments were made to special committees of the Association previously authorized:

Committee on Federal Health Legislation

Chairman, Lee K. Frankel, Ph.D.

James A. Tobey, Dr.P.H.

M. J. Rosenau, M.D.

S. J. Crumline, M.D.

Committee to Coöperate with Director of the Census

Chairman, Charles V. Chapin, M.D.

Secretary, Haven Emerson, M.D.

Irving Fisher, Ph.D.

Committee to Extend the Association's Influence in South and Central Americas

Chairman, Hugh S. Cumming, M.D.

Professor E. O. Jordan

John A. Ferrell, M.D.

Professor E. O. Jordan, Robert Spurr Weston and William H. Park, M.D., were appointed as members of the Sedgwick Memorial Medal Committee. Professor C.-E. A. Winslow was appointed delegate and Lee K. Frankel, Ph.D., alternate to the Joint Committee on the Grading of Nursing Schools.

Section Committees—The Executive Secretary reported that 44 replies had been received to the inquiry addressed to the 59 Section committees with reference to their scope and status, and the Board confirmed the appointment of these 44 committees and appointed a special committee of 3 to study with the Executive Secretary the relationship of these committees to the work of the Association and to present recommendations for allocation of these committees under the four standing committees of the Association.

Committee on Research and Standards—Abel Wolman was designated as *Chairman* of the Committee on Research and Standards.

Representation at Foreign Meetings

—The Chairman of the Board was authorized to appoint delegates to attend the following meetings to be held in Europe this summer:

International Congresses on Hygiene, Dresden, Germany, May to Oct.

Congress of the Royal Sanitary Institute, Margate, England, June 21-28

Congress of the Royal Institute of Public Health, Portsmouth, England, June 4-9

ARTHUR TOMALIN

Arthur Tomalin, a member of the Public Health Education Section of the American Public Health Association, and Associate Secretary of the Association from June, 1927, to June, 1928, died on February 8 at his home in Mountain Lakes, N. J.

Mr. Tomalin came to the A. P. H. A. from *Pictorial Review* where he had been managing editor. Previous to this he was director of publications of the American Child Health Association. There he made a notable contribution to public health periodicals in developing the splendid though short lived *Child Health Magazine*. Mr. Tomalin was considered one of the most capable magazine executives of the day. His most important contribution to the A. P. H. A. was the present format of the JOURNAL.

Mr. Tomalin had an abundant measure of those lovable human qualities that endeared him to all who were associated with him. His loss will be felt by a host of friends made in many fields during an exceptionally active life.

HEALTH SURVEY OF WASHINGTON, D. C.

At the invitation of the Washington Council of Social Agencies, representatives of the Committee on Administrative Practice of the American Public Health Association are undertaking a health and hospital survey of the City of Washington. The chairman of the local health committee of the Council of Social Agencies is Dr. Paul Preble, U. S. Public Health Service.

The survey has the approval of the local health department and while similar to studies made in other cities will include special studies of public health nursing, social hygiene, and certain aspects of hospital administration. Representatives from the National Organization for Public Health Nursing and the American Social Hygiene Association will investigate problems in their respective fields, and questions relating to hospital administration will be considered by specialists suggested by the American Hospital Association.

NEW MEMBERS

Charlotte Addison, B.Sc., Pittsburgh, Pa., Director, Nutrition Department, Western Pennsylvania Hospital

Mabel Baird, Hartford, Conn., Field Secretary, State Tuberculosis Commission

Franklin W. Barrows, M.D., New Rochelle, N. Y., School Medical Supervisor, Board of Education

Alga M. Beck, Brooklyn, N. Y., Teacher, Maxwell Training School

W. D. Bishop, M.D., Greenville, O., Health Commissioner

Miranda Bradley, R.N., Riverhead, N. Y., County Supervising Nurse

John Brown, Jr., M.D., New York, N. Y., Secretary, Department of Physical Education, National Council Y. M. C. A.

Freda M. Caffin, San Francisco, Calif., Field Supervisor, Stanford Social Service

K. Frances Cleave, Detroit, Mich., Director, DuBois Health Center

Alice Cunningham, Lodi, N. J. (Assoc.)

Mrs. Sigrid M. Dudley, Menasha, Wis., School Nurse

Charles Eastman, D.V.M., Los Angeles, Calif., Junior Veterinarian, Los Angeles County Health Department

Louis E. Eslick, M.D., Rockwell City, Ia., Chairman, Public Health Committee of the City Council

Dr. Juan Farill, Mexico City, Mex., Chief Quarantine Officer

Dr. J. M. Farrell, Wichita Falls, Tex., Chief City Sanitary Inspector

- Florence E. Ferguson, R.N., Lemars, Ia., School Nurse
- Morgan B. Finley, San Benito, Tex., County Sanitarian
- Roy P. Forbes, M.D., Denver, Colo., President, Denver Public Health Council
- Mary G. Fraser, R.N., Miami, Fla., Supervisor of Nurses, Department of Health
- Foribio Garcia, M.D., N. Laredo, Mex., Delegado Sanitario Federal
- Helen Hackney, Providence, R. I., Teaching Health, Nickerson Settlement House
- Lillie M. Hall, R.N., Havre, Mont., Hill County Public Health Nurse
- Dr. Edward R. Hays, Falls City, Nebr., City Physician
- Dr. Charles S. Holt, Fort Smith, Ark., President, Fort Smith District Health Association
- Albini Jeannotte, M.D., Temiscaming County, Que., Medical Health Officer
- George J. Kappler, West Palm Beach, Fla., City Bacteriologist, Department of Health
- Florence B. Kenworthy, Dayton, O., Social Worker, Montgomery County Children's Home
- J. C. Laney, San Antonio, Tex. (Assoc.)
- Harvey H. Latson, M.D., Amarillo, Tex., City Health Officer
- Henry C. Lawton, M.D., Camp Hill, Pa., Secretary, Board of Health
- Jacob D. Leebron, Philadelphia, Pa., Assistant Immunologist, Department of Health
- Daniel A. MacPherson, Ph.D., Chapel Hill, N. C., Professor of Bacteriology and Public Health, University of North Carolina
- Anna H. McCarthy, R.N., Fargo, N. D., Supervisor of Nurses
- Alfred R. McGonegal, Washington, D. C., Chief Plumbing Inspector
- E. Franc Morrill, M.D., Rock Island, Ill., Director, Life Extension Department, Royal Neighbors of America
- Ruth G. Nystrom, M.D., Minneapolis, Minn., Charge of Prenatal Clinic of Child Welfare Association
- Bernard L. Plouffe, M.D., Webster, Mass., Chairman, Board of Health
- Dr. E. Potvin, Chicoutimi, P. Q., Health Officer
- Charles R. Smith, M.D., Decatur, Ill., Director of Public Health
- Thomas B. Snoddy, M.D., White River, Ariz., U. S. Indian Field Service
- Holman Taylor, M.D., Fort Worth, Tex., Editor, *Texas State Journal of Medicine*
- Dr. J. H. Toussaint, Thetford Mines, P. Q., Medical Health Officer
- Henry S. Turrill, M.D., Kent, Conn., Health Officer
- T. H. Valentine, M.D., Lawrenceville, Va., Director, Brunswick-Greenville Health Unit
- C. McA. Wassell, M.D., Little Rock, Ark., Director, Pulaski County Health Unit
- L. J. Zoeller, Ivorydale, O., Industrial Personnel, Procter & Gamble Co.

DECEASED MEMBERS

- Frederick Montizambert, M.D., Ottawa, Ont., Honorary Fellow and Past President
- Ivan C. Weld, Washington, D. C., Elected Member 1914
- A. C. Burnham, New York, N. Y., Elected Member 1922
- J. A. Frank, M.D., Columbus, O., Elected Member 1927

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Chicken Pox—Taking advantage of the control measures available only in hospitals an effort has been made to determine the approximate incubation period of chicken pox. These observations were made at the Herman Kiefer Hospital, which is the contagious disease institution of the Detroit Health Department. In a study of 67 cases it was found that most secondary cases showed eruptions from 13 to 17 days after lesions appeared in the primary case. The median in these studies seemed to be the 15th day. It was also found that infectivity during convalescence is less prolonged than commonly considered; does not necessarily coincide with the persistence of crusted lesions; and probably ceases within 10 days. It would also appear that chicken pox was not infectious 24 hours preceding the eruption.

Human convalescent serum constitutes the only medium for procuring passive immunity to infectious diseases of unknown cause. Such serum has been used extensively in this institution to prevent the spread of chicken pox imported through concurrent infections. It has been found that convalescent serum furnishes a high degree of protection if obtained from the donor within 1 month of the appearance of the eruption. Thereafter the protection is less marked, and when the period has been extended to 5 months, only one-third of the immunized susceptible patients are protected. Having taken into account a corrective factor for the normal incidence of chicken pox in any unprotected group, it has been found that the protective power of convalescent chicken pox serum varies from 91 per cent for

serum from early convalescence to 35 per cent when the serum is obtained 5 months or more after the acute attack. —J. E. Gordon and F. M. Meader, *J. A. M. A.*, 93: 2013 (Dec. 28), 1929.

Financial Aid for County Health Work—State aid for county health work may be used to encourage the undertaking of new activities, provide a means through which the state may discharge its responsibility to local government, and assist in relieving the relatively poor local community of its financial burden. State aid may be a specific sum based upon a standard type of organization, or the amount may vary with the size of organization and resources of the area. Another suggested method is to fix upon a subsidy based on the size of population served and quite independent of the type of organization, this in turn being increased or decreased, depending upon the resources of the local area. It is suggested that the desirable features of both methods may be had by fixing the subsidy as a certain percentage of the amount appropriated by the local area. —E. Sibley and J. W. Mountin, *Apportionment of Financial Aid for County Health Work*, *Pub. Health Rep.*, 45: 1 (Jan. 3), 1930.

Smallpox Prevalence — Among other matters the Permanent Committee of the International Office of Public Hygiene at its meeting held in Paris in May, 1929, considered the persistent prevalence of mild smallpox of the alastrim type in Great Britain and the United States during the past decade. The question has arisen as to whether it

would not be advisable to differentiate in administrative statistics between the mild smallpox and the classic smallpox which prevails in different countries of the Far East.

Postvaccinal encephalitis does not disappear from countries where it has made its appearance. The incidence of this complication varies greatly in the countries for which reports are available.—*Pub. Health Rep.*, 45: 18 (Jan. 3), 1930.

National Leper Home—During the fiscal year ending June 30, 1929, there were admitted to the National Lepro-

sarium at Carville, La., 49 new patients. During this same year 109,685 hospital days were furnished, 15 patients left the premises without leave, 9 of which were readmitted, and 13 died. The promising advances made in the treatment of leprosy are indicated in the fact that 19 patients were paroled as being no longer a menace to public health and 6 other patients complied with the requirements for parole but owing to inconvertible disfigurements chose to remain at the institution.—O. E. Denney, Annual Report of National Leper Home, 1928-29, *Pub. Health Rep.*, 44: 3169 (Dec. 27), 1929.

LABORATORY

C. C. YOUNG, D. P. H.

THE USE OF SODIUM HYPOCHLORITES TO PRESERVE MILK

WALTER S. DAVIS

*Division of Laboratories and Research,
New York State Department of Health, Albany, N. Y.*

THE literature contains numerous reports on the use of hypochlorite solutions and chlorine as preservatives in milk which do not encourage their use because of the odors and tastes produced.^{1,2,3,4} Nevertheless, many sanitary inspectors and others interested in safe milk supplies believe that these compounds are often successfully used for this purpose. A few tests were recently made in this laboratory on the effect of sodium hypochlorite added to milk in order that the results might be used as a basis for a definite conclusion.

Different dilutions of a proprietary preparation containing sodium hypochlorite were added to milk with an initial plate count of 120,000. Counts

were made after 2 hours at 20° C., and also for 2 hours at 20° C. followed by 16 hours at 5° C. The tastes and odors were observed and the Rupp test⁵ for the presence of chlorine was made. The results indicate that when the solution was added to milk in a concentration of 1:5,000 of available chlorine, there was no reduction in the bacterial content in 2 hours, and, after acting for 18 hours, the original count of 120,000 was only reduced to 76,000 and the milk had an unpleasant taste and odor. In a concentration of 1:1,000 the count after 18 hours was 28,000. A chlorinous odor and taste were detected even in milk treated with a concentration of only 1:20,000 and they were very no-

ticeable in concentrations of 1:10,000. The Rupp test gave a reaction in a concentration of 1:20,000 and a strong reaction in a concentration of 1:10,000.

CONCLUSIONS

Preparations containing sodium hypochlorite will not materially reduce the bacterial count in milk when used in concentrations as high as 1:5,000. When used in dilutions of 1:20,000, taste and odor may be detected and are noticeable in concentrations of 1:10,000. The unpleasant taste and odor produced when sodium hypochlorite is added to milk in a sufficient

quantity to act as a preservative render its use impracticable.

A LOW READING TURBIDIMETER

AUGUST V. GRAF, F. A. P. H. A.

*Chief Chemical Engineer, St. Louis Water Works,
St. Louis, Mo.*

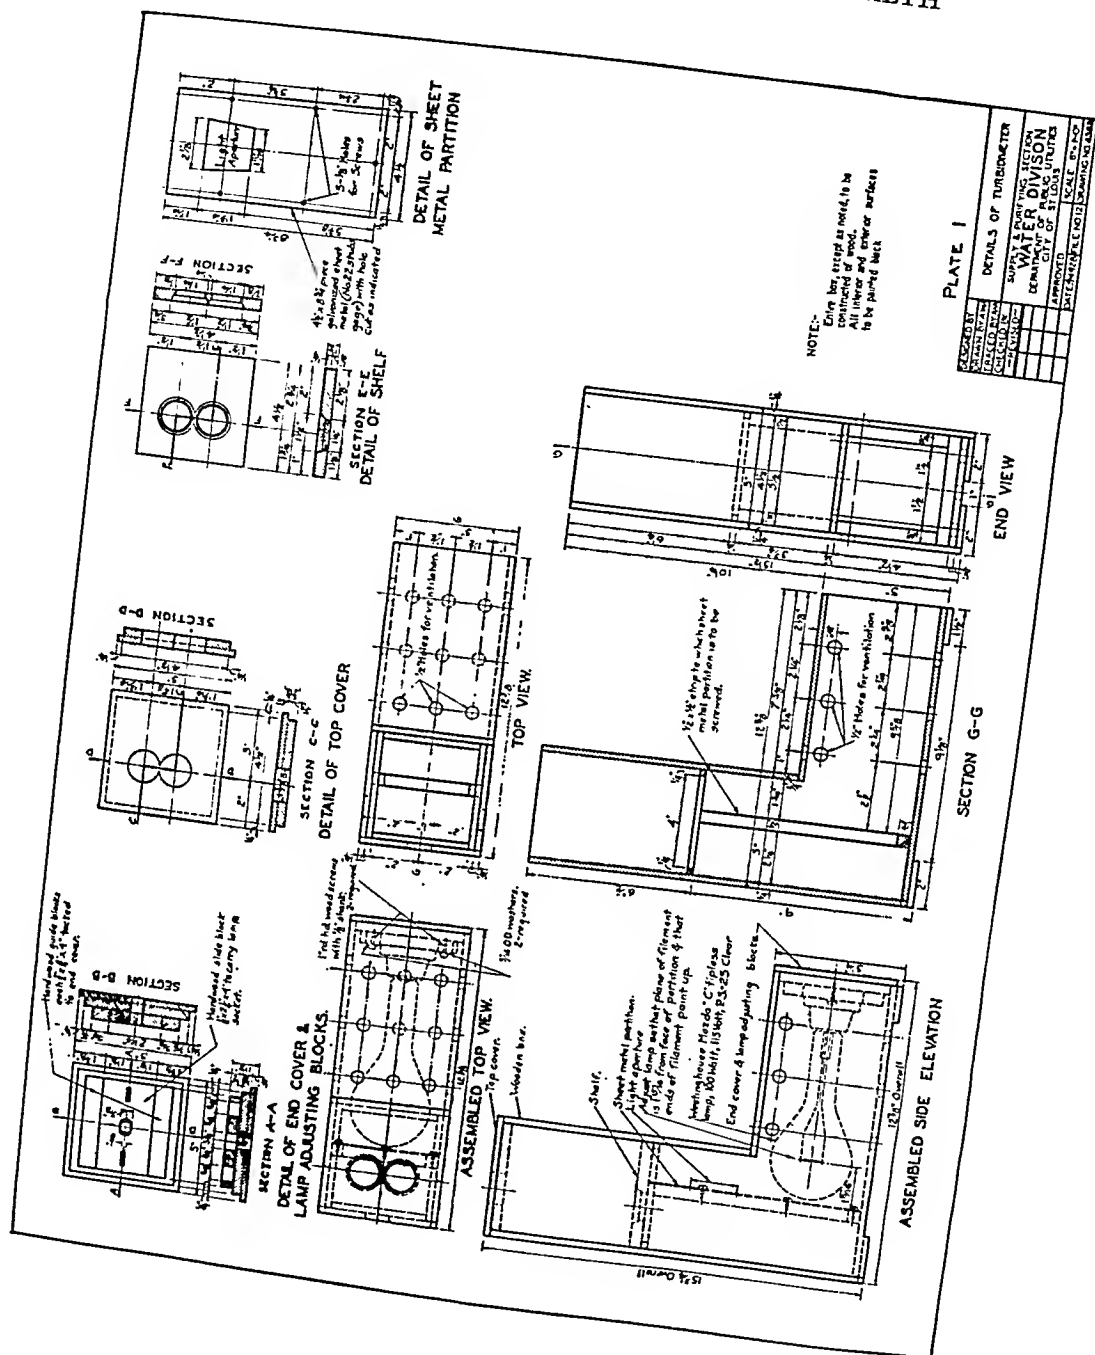

TURBIDITIES of less than 5 p.p.m. are hardly noticeable when water is observed in a glass or other container and, as a result, some plants are satisfied if the effluent from their filters contains less than this amount. As far as the turbidities are concerned they are of no moment because that small amount of suspended matter is not objectionable from an esthetic viewpoint, but the plant is not producing an effluent that good design and operation warrant. Also the removal of bacteria is accomplished by the same agency that removes turbidity, although the relation is not definite because of the variation in size of both the bacteria and suspended matter.

Comparing the filter effluent with standards containing known amounts of silica is not satisfactory when low turbidities are to be determined. As a result of our desire to maintain an effluent free from turbidity, the box to be described was designed.

CONSTRUCTION OF BOX

The entire box, except the partition, is constructed of wood and painted black, both inside and outside. The partition of galvanized sheet metal is also painted black. All inside measurements of the box and parts should be made exactly as indicated because the dimensions locating the normal position of the light filament, the light aperture in the partition and the circular openings in the shelf are important.

The position of the light aperture and the openings are fixed but that of the light filament is adjustable. This was made so to take care of slight variations in the shape and position of the filament in the lamp. The filament may be moved closer to or farther from the partition by adjusting the metal contact in the light socket; and shifted from side to side by means of the sliding block which carries the lamp. The position of the filament from top to bottom is fixed; the open end should point

up. The position need be fixed but once for each lamp.

Ventilation is provided by the circular openings in the box but the lamp should be lighted only when the box is in use.

PREPARATION OF STANDARDS

The tubes for making the turbidity determinations should be clear glass, 100 c.c., short form Nessler tubes, free from scratches or other imperfections. These should be scrupulously clean at all

times. Fresh standards should be prepared each day from a stock suspension, the turbidity of which should be 10 p.p.m., so that when 1 c.c. of the suspension is made up to 100 with turbidity free distilled water, a standard containing 0.1 p.p.m. will be obtained. The suspension containing 10 p.p.m. can be made from one containing enough turbidity to be determined by the Jackson candle turbidimeter and diluted to yield the desired standard stock suspension. The standards to be prepared will depend upon the turbidity of the water being tested. Experience will soon enable the observer to reduce the number of standards required to a minimum.

DETERMINATION OF TURBIDITY

Introduce 100 c.c. of the sample in one of the tubes and set it into one of the holes in the shelf. After all air bub-

bles have risen to the surface, the sample is ready for comparison with the standards. If the sample is filtered water of low turbidity, the standard of 0.5 p.p.m. may be prepared and set in the other hole in the shelf and after all air bubbles have disappeared, the comparison may be made. If the turbidity of the sample is less than 0.5, estimate and prepare a weaker standard; if greater, prepare a standard of greater turbidity.

The principle involved is the observation, against a dark background, of the suspended particles in the sample illuminated by admitting light rays at an angle, through the bottom of a glass tube contained in a dark chamber.

The original box was designed by August G. Nolte and the writer. The box as shown is an outgrowth of the original, changes having been suggested by other members of the laboratory staff.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

VITAL STATISTICS FOR 1929

New York, N. Y.—Despite the handicap imposed by the outbreak of influenza in the early part of the year, through which the city lost about 4,000 lives above the normal, the year 1929 registered a death rate of 12.78 per 1,000 population as against a rate of 12.98 in the previous year. Infant mortality for 1929 was 59 per 1,000 live births as against 66 for 1928. All communicable diseases, typhoid, measles, scarlet fever, whooping cough, diphtheria and croup, showed substantial decreases over 1928. Increases in rates since 1928 were shown for organic heart disease, 288.1 per 100,000 as compared with 277.0; cancer, 129.4 and

128.4; influenza, 19.8 and 14.9; and diabetes, 28.4 and 27.6. Pneumonia showed a decreased rate for 1929, 156.0 compared with 166.5 for 1928; nephritis showed a rate of 52.4 for 1929 compared with 57.0 for 1928. There was an increased mortality from accidental deaths, 78.6 per 100,000 compared with 76.3 in 1928; of these, vehicular accidents showed a rate of 23.2 against 19.2 in the preceding year.—*New York City Week. Bull.*, 19: 3 (Jan. 4), 1930.

Detroit, Mich.—In general, the health situation during 1929 was better than in 1928. The death rate of 11.5 per 1,000 population was slightly lower than that of 1928. There were 33,500 births, representing a rate of 23.4 per 1,000

population, the same rate as in 1928. There was a gratifying decline in infant mortality, the rate dropping from 77.6 in 1928 to 69.3 in 1929, the lowest rate ever experienced in Detroit. Significant decreases were shown for tuberculosis, 94.8 to 93.0; pneumonia, 135 to 119; measles, 11.8 to 2.1; and scarlet fever, 4.7 to 3.7. The typhoid fever death rate, 0.9, was the lowest ever reported for Detroit. An increase was shown in the diphtheria death rate which rose from 16.3 in 1928 to 21.8 in 1929.—*Detroit Week. Health Rev.*, Jan. 4, 1930.

San Diego, Calif.—The latest U. S. Bureau of the Census population estimate for the city as of July 1, 1928, was 119,700. During 1929, the Department of Public Health registered 2,485 live births, giving a birth rate of 20.8 per 1,000 estimated population, as against 22.0 in 1928. There were 2,158 deaths registered, equivalent to a death rate of 18.0 per 1,000 population compared with 18.7 in 1928. In 1929, there were 121 deaths of infants under 1 year of age, a rate of 48.7 per 1,000 live births as against 48.0 in 1928. There were reported 1,042 personal injuries resulting from motor vehicle accidents as against 1,033 in 1928; there were 63 deaths from automobile accidents, 12 of which were children under 15 years of age. For 1929, the total death rate from automobile accidents was 52.6 per 100,000 estimated population as against 50.1 in 1928. The rates for 1929 are the highest ever attained in San Diego.—*San Diego Month. Bull.*, Dec., 1929.

Racine, Wis.—Present indications are that the death rate for 1929 will be 8.9, which is the same as for 1928; the birth rate will be 19.7 as compared with 19.3 in 1928; the infant death rate will be 53.1 compared with 48.7 in the preceding year. The estimated population for 1929 was 78,300. Rates per 100,000 population that decreased since

1928 were heart disease, 206 to 156; tuberculosis, all forms, 60 to 55; diseases of early infancy, 48 to 25; maternity, 16 to 10; automobile accidents, 16 to 14. Among those that increased from 1928 to 1929 were cancer, 85 to 98; apoplexy, 57 to 74; pneumonia, all forms, 69 to 84; and kidney diseases, 33 to 44. Contagious diseases as a whole decreased from 52 to 38 per 100,000 in 1929.—*Racine, Wis. Month. Bull.*, Jan., 1930.

Syracuse, N. Y.—The Health Department of Syracuse has reported the estimated population for 1929 as 201,645. The general death rate per 1,000 population was 13.0 as compared with 13.5 in 1928; the birth rate per 1,000 population was 21.0 in 1929 and 21.5 in 1928. The infant mortality rate declined from 58.9 per 1,000 live births in 1928 to 55.7 in 1929. Deaths from heart diseases resulted in 604 deaths in 1929 as against 598 in the preceding year. Diseases showing decreases since 1928 were cancer, 289 to 279; cerebral hemorrhage, 232 to 209; nephritis, 202 to 189; pneumonia, 267 to 266; and tuberculosis, 96 to 65. There were 5 deaths from scarlet fever as against 3 in 1928, but no other communicable disease showed an increased mortality.—*Syracuse Month. Bull.*, 5: 8 (Jan.), 1930.

Dayton, O.—The most important item in the health situation during 1929 was the infant death rate that fell from 66.2 per 1,000 live births in 1928 to 63 in 1929. The birth rate for 1929 was 18.4 compared with 17.7 in 1928. The general death rate for 1929 was 11.6 per 1,000 population as compared with 11.4 in 1928. Organic heart disease remains the leading cause of death, 534 deaths resulting in 1929 as against 412 in 1928. The increasing virulence of scarlet fever is indicated by 6 deaths in 1929 whereas in the 5-year period 1922-1926 the deaths only averaged 2 per year although the number of cases was

much higher. Suicides nearly doubled in 1929, the number reaching 35 as against 19 the preceding year. Other diseases showing increased deaths for 1929 were influenza, 60 as against 52 for 1928; cancer, 199 and 197; pulmonary tuberculosis, 115 and 113; and accidents, 154 and 122. Pneumonia deaths fell from 173 to 163 in 1929, and nephritis from 86 to 73.—*Dayton, Ohio, Health Bull.*, Jan. 1, 1930.

Cattaraugus County, N. Y.—A provisional forecast of vital statistics for 1929 indicates that the death rate will be about 13.2 as compared with 13.8 in 1928. The births are distinctly fewer than last year. The most striking figure is the infant mortality, so far 28 fewer infant deaths being reported in 1929 than in 1928, making a provisional rate of 52 for 1929 against 70 the year before. There are only 2 deaths from diarrhea and enteritis under 2 years compared with 5 in 1928. Maternal mortality, 6 per 1,000 total births, is somewhat lower than 1928. Tuberculosis deaths are only slightly above 1928, indicating a rate under 50. One death from typhoid is recorded in 1929. Other communicable disease deaths are fairly comparable with the experience of recent years. Mortality from respiratory diseases reflects the prevalence of influenza during the first 3 months of the year.—*New York Health Demonstrations*. Milbank Memorial Fund, Jan. 15, 1930.

Illinois—The general death rate for 1929 appears to have been on a level with that of 1928, a figure a little higher than the average for recent years. Infant mortality, on the other hand, appears to be the most favorable ever experienced by the state. Mortality from influenza was considerably higher in 1929 than the year before, most of the deaths occurring in the first 3 months. Tuberculosis was down to a new low level, with 4,845 deaths for the first 11 months against 4,974 for the corre-

sponding period of 1928. Diphtheria showed a very bad record, 8,500 cases, the highest number reported since 1923. Mortality from pneumonia behaved very much like that of influenza, case reports being under the 1928 figure by nearly 4,000. Prevalence of measles was five times greater in 1929 than in 1928. Both cases and deaths from scarlet fever were sharply above the average in recent years. The 4,227 cases of smallpox gave Illinois the worst record since 1921, and the worst record of any state for 1929.—*Illinois Health Messenger*, 2: 101 (Jan. 15), 1930.

Ohio—There were 3,726 more deaths in Ohio during the first 10 months of 1929 than during the corresponding period of 1928, or an increase of 12 deaths per day. Influenza showed the greatest increase in the number of deaths, 1,790, and the rate increased from 35.3 to 66.6; heart disease was second, the rate increasing from 211.2 to 217.4; whooping cough showed an increase of 320 deaths and automobile accidents 299. Other causes of death showing slight increases were: measles, scarlet fever, cerebral hemorrhage, railroad and street car accidents, suicides and homicides. Decreases were recorded in the number of deaths from diphtheria, rabies, tuberculosis all forms, cancer all forms, diarrhea and enteritis under 2 years, nephritis, and the puerperal state. For the first 10 months of 1929 there were 68,362 deaths, with a rate of 12.2 per 1,000 population compared with 64,636 for 1928, a rate of 11.6.—*Ohio Health News*, 6: 3 (Jan. 15), 1930.

Principal Causes of Death in 1928
—U. S. Department of Commerce announced that 1,378,675 deaths occurred in 1928 in the registration area in continental United States, corresponding to a death rate of 12.0 per 1,000 population, as compared with 11.4 in 1927. The area for 1928 comprised 95.4 per cent of the population of United States

as against only 91.3 per cent in 1927. Increases in rates per 100,000 population for 1928 over those of the preceding year occurred from diseases of the heart, 195.7 to 207.7; cerebral hemorrhage and softening, 84.0 to 87.0; nephritis, 92.5 to 95.0; diabetes mellitus, 17.5 to 19.0; influenza, 22.6 to 45.2; and pneumonia, all forms, 80.5 to 98.0. Increases were shown also for cancer, all accidental causes, automobile accidents, measles and pellagra. Significant among decreases in rates from 1927 to 1928 were those from tuberculosis, all forms, 80.8 to 79.2 and from congenital malformations and diseases of early infancy, 67.7 to 65.6. Other causes that showed decreased death rates for 1928 were railroad and mine accidents, scarlet fever, acute poliomyelitis, typhoid and paratyphoid fever, diarrhea and enteritis under 2 years, and whooping cough.—U. S. Department of Commerce. *Press Release*, Dec. 11, 1929.

Health of New Zealand—The annual report for New Zealand for 1928 showed a slightly higher death rate and a falling birth rate. The death rate was 8.49 per 1,000 population, an increase of 1.7 per cent over the preceding year. Infant mortality was 36.18 per 1,000 births, against 38.74 in 1927. This phenomenally low level has never before been attained in New Zealand or in any other country in the world. The birth rate was 19.56 per 1,000, the number of births, 27,000, being much the lowest for the past 9 years.

The tuberculosis death rate was 5.02 per 10,000 population, which places New Zealand in a better position than other countries. Mortality from cancer showed an increase over 1927, the rate being 9.87 per 10,000 population. During 1928, of all persons over 40 years of age whose deaths were registered, 1 in every 7 males and 1 in every 6 females died from cancer. Scarlet fever

has been epidemic the past 2 years. For 1928, case mortality of 0.89 per cent showed an increase over the rate for 1927, 0.73. Influenza showed an increase and a higher death rate, 1.74 per 10,000, and diphtheria a slight increase, while measles and whooping cough were much less prevalent. Typhoid is still rare. There was one outbreak of dysentery.

Maternal mortality remained at practically the same level, 134 in 1928 as compared with 137 in 1927. The rate per 1,000 births increased slightly from 4.91 to 4.93 because of the lower number of births in 1928.—*J. A. M. A.*, '93: 1906 (Dec. 14), 1929.

Respiratory Infections in Massachusetts in 1928-1929—This is a report by the Massachusetts Department of Public Health of a survey of the epidemic of respiratory diseases made during the winter 1928-1929. The method of survey developed by the U. S. Public Health Service was used and applied to 4 widely scattered communities. The data on 10,000 persons were pooled with 5,000 obtained from Boston. These results were compared with current information obtained from various sources. Beginning the middle of December, and extending through January, daily reports from district health officers as to the number of pneumonia deaths in 6 of the principal cities were obtained. These reports represented about 1,400,000 persons or about one-third of the population of the state. In addition, weekly reports on the total numbers of respiratory disease cases were sent by 200 physicians throughout the state.

Three industries, two public utilities representing over 7,000 persons and a department store employing 4,000 persons, furnished their daily absenteeism from respiratory diseases for this year and last year. Beginning with December 22, the respiratory cases of the survey and the reports of influenza paral-

leled each other in their abrupt rise. During the critical period up to the middle of January, the doctors' replies, the data from Plant I and the department store, and the reported pneumonia cases followed each other quite closely. The cases for Plant I and the survey were similar. The situation for Plant II was more like that for the pneumonia deaths. Four large hospitals reported no increase in sickness in their staff, nor anything unusual in the number of pneumonia admissions.

The findings on the 15,000 persons in the 5 communities surveyed, showed that the highest rates of weekly increase were from December 22 to January 19, which was the peak. The increases varied from nothing to 200 per cent. In Boston, but not elsewhere, the females showed a higher morbidity rate than the males. The 0-9 age group in the total survey showed the highest rate, 34.3 per 100 population and the 20-29 and 50-59 age group the lowest, 24.2 and 25.6, respectively. Physicians were employed by all individuals with pneumonia, three-quarters of those with influenza, two-thirds of those with grippe and one-fourth of those with colds. During the 3 months studied, 2.5 per cent of the patients had more than one attack with an average interval of 32 days between. The epidemic was about half as severe as that of 1920 and one-eighth as severe as 1918. About one-quarter of the population was sick with respiratory diseases and about one-eighth was sufficiently sick to remain in bed 3 days or more.—H. Bigelow and

H. L. Lombard, *New England J. Med.*, 201: 474-478 (Sept. 5), 1929.

Incidence of Heart Disease in the Pacific Northwest—The data for this study were obtained from 5,489 patients presenting themselves in private practice and in 23,172 admissions to five hospitals, all from one locality in the Pacific Northwest. In this group, there were 13,258 medical patients, of whom 3,488, or 26 per cent, showed cardiovascular disease. Acute rheumatic fever showed a low incidence, 0.1 per cent as compared with 5.8 to 0.2 per cent in other localities. Goiter, being endemic, showed an incidence of 6.1 per cent of medical patients producing cardiovascular symptoms severe enough to send the patients to the hospital. Hypertensive cardiovascular disease showed a high incidence, 26.0 per cent, as in other localities. Records of 1,673 private patients with cardiovascular symptoms were studied as to etiological, structural and functional diagnoses. Hypertensive cardiovascular disease was the most frequent of all types, causing 56.3 per cent. In the goiter group, there were 144 cases, or 8.6 per cent of the total cardiovascular group, who showed various degrees of effect upon the heart. In addition to the cardiovascular group, 651 patients came for heart examinations in whom no heart disease was found. In 465 autopsies at the Good Samaritan Hospital, 96 showed cardiovascular lesions as the cause of death.—T. H. Coffen, *Am. Heart J.*, 5: 99-103 (Oct.), 1929:

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Researches on Typhoid Carriers—The author carried out investigations to determine when the typhoid bacillus first appears in the feces of typhoid patients as well as to ascertain the time which elapsed between the cessation of acute clinical symptoms and the disappearance of the pathogenic organisms from the stools. Daily bacteriological examinations of the stools of 16 patients in the early stage of the disease showed that elimination of the typhoid bacilli through the intestine began early, in 1 case even on the 4th day. The number of bacilli so eliminated increased until the 2d week and the first days of the 3d week. Subsequently the elimination of the bacilli gradually diminished. In 2 cases, however, the typhoid bacillus was found in the excreta 5 months after clinical recovery.

The author also examined the feces of 100 typhoid convalescents and found that 67 (22.33 per cent) were carriers 1 month after clinical recovery, 26 (8.66 per cent) after 2 months recovery, 12 (4 per cent) after 3 months and only 4 (1.3 per cent) were chronic carriers. The best results were obtained with Drigalski-Conradi and Endo's media to which a little crystal violet had been added.—A. Leoni, *Bol. d. Inst. Sieroterap. Milanese*, 7: 479-495, 1928.

An Unusual Water Works—The Philips Glow Lamp Works requires a water supply of about 2 m.g.d. with little CO_2 and iron and no manganese. The raw water, from deep wells, contains 20-25 p.p.m. CO_2 ; 2-3 p.p.m. iron; and 0.3-0.4 p.p.m. manganese. This is treated in a plant consisting of jet aerators, with detention of 1 hour,

and two sand filters in series. Potassium permanganate is added between the filters. The filters are cleaned with air as well as with water. The effluent contains 2-4 p.p.m. CO_2 ; 0.1 p.p.m. iron; and no manganese.—W. Rudolfs, *Water Works*, 67, 1: 7, 1928 (from Papers of Water Pollution Research Board, England).

The Activated Carbons and Their Use in Removing Objectionable Tastes and Odors from Water—The author considers that owing to the increase in the pollution of water supplies by industrial wastes, it is essential to find a simple and reliable method to remove tastes and odors from drinking water, and suggests the use of activated carbons. Carbon, bone charcoal and vegetable charcoal are already used extensively in filters for adsorbing coloring matter and purifying oils, sugars, etc. Activated carbon is prepared by heating carbon in closed retorts in the presence of air, steam, carbon dioxide or chloride at a temperature of about 900°C . Its adsorptive property is supposed to be due to the free valencies of the carbon atoms on the amorphous surface of the material. Activated carbon may be revived by heating, by heating and treating with an acid or alkali, or by passing steam through the filter, according to the material adsorbed.

After giving a brief survey of the various methods, such as superchlorination and dechlorination with sulphur dioxide, and treatment with ammonia or permanganate to remove chloro-phenol tastes from water, the author describes his experiments on removal of phenols and dechlorination with activated car-

bons. Water polluted with ammonia still wastes from a coke-oven plant was passed through a 27" filter, composed of Darco (one of the active carbons) and bone charcoal, at the rate of 2 gal. per sq. ft. per min. The amount of phenols in the polluted water was gradually increased, and chlorine was added to the filtrate. No taste was noticed until the initial amount of phenol reached 100 p.p.m., and a trace of phenol could be detected in the effluent. Similar tests made with Minchar, another activated carbon, gave tastes in the filtrate from a solution containing only 4 p.p.m. of phenols. The adsorptive capacities of Darco, Minchar and bone and wood charcoal were tested by adding 1 gm. samples to 1-litre solutions containing various quantities of phenol. The adsorptive capacity of Darco was found to be about 0.5 per cent of its weight. Darco weighs about 18 lb. per cu. ft., so that a filter bed 2 ft. deep will remove about 0.18 lb. of phenol per sq. ft. As water rarely contains more than 0.005 p.p.m. of phenol, water could be filtered at the rate of 2 gal. per sq. ft. per min. for nearly 4 years before the Darco would be so saturated with phenol that an amount sufficient to produce a taste would pass the bed.

For waters which are polluted with a variety of compounds, the addition of excess chlorine to break down the compounds, followed by dechlorination with active carbon, is probably the best method of purification. Dechlorination with active carbon has already been used by the Candy Filter Company in England for 19 years. The first dechlorinating experiment was made to dephenolate a Darco filter. After running chlorinated Chicago water through the filter at a rate of about 13.4 gal. per sq. ft. per min., the residual chlorine was removed and the carbon was re-vivified. The amount of chlorine was increased to as much as 3,000 p.p.m.

and the water filtered at the rate of about 2 gal. per sq. ft. per min. Even under these conditions the carbon was able to remove all the residual chlorine and did not appear to have lost its activity after being in contact with the strong chlorine solution.

The use of activated carbons for reducing the oxygen demand of polluted waters was also investigated and satisfactory results were obtained. As the carbon actually removes certain compounds from the water, filtration should be more efficient than the addition of one compound, such as chlorine or sulphur dioxide, which only converts offensive into inoffensive compounds. It is suggested that an effluent from a sewage disposal plant might be converted into palatable water by the processes of aeration, filtration through rapid sand filters, excess chlorination and a final filtration through a bed of activated carbon.

A short description is added of the construction of carbon filters and the best method for including them in the water works. Carbon filters should be built on the same plan as rapid sand filters, but used with an upward instead of a downward flow. It is calculated, assuming the average water consumption to be 150 gal. per head per day, that the installation of carbon filtration would raise the cost per head per year from \$1 to \$1.50, in the average city in the country.—J. R. Baylis, *J. Am. Water Works A.*, 21: 787, 1929 (from papers of Water Pollution Research Board, England).

B. Coli Isolation on Solid Media: Relation of Direct B. Coli and B. Aerogenes Counts—Separate *B. coli* and *B. aerogenes* estimations by direct plating methods, using cyanide-citrate-agar as a differential medium, suggested the use of such determinations in the judgment of true fecal pollution. A quantitative study of the *B. coli* and *B.*

aerogenes content of human and animal feces, sewage, cereals and soils gave the following ratio:

	<i>B. coli</i>	Ratio of to <i>B. aerogenes</i>
Human feces	182	" 1.0
Animal feces	145	" 1.0
Sewage (Chicago district)	1	" 1.4
Cereals	1	" 16.0
Soils	1	" 225.5

—F. O. Tonney and R. E. Noble, *Canad. Eng.*, 57, 5: 270, 1929 (from papers of Water Pollution Research Board, England).

Increasing Capacity of a German Sludge Digestion Plant—The efficiency of a sludge digestion tank at the Essen-Nord plant was increased 100 per cent by installing two screw pumps to agitate the sludge. The pumps lift ripe sludge from the bottom and sprinkle it on the surface. They can also be reversed to mix scum from the top with ripe sludge.—A. Kozma, *Eng. News Rec.*, 100, 9: 362, 1928 (from papers of Water Pollution Research Board, England).

Sludge Disposal at the Calumet Sewage Treatment Works—The Calumet sewage treatment works deal with sewage from part of south Chicago and several small municipalities. The capacity of the plant is 56 m.g.d. with an allowance for a 50 per cent storm flow increase. The sewage passes through a rack screen and grit chambers to 30 Imhoff tanks. The sewage is mainly domestic, but some trouble has been caused by paint waste. The direction of flow through the tanks is reversed at short intervals. The design of the sludge hoppers and the method of removing the sludge, which has an average content of 87.8 per cent moisture, are described. The sludge is laid on drying beds to a depth of 9–11" and after 2 months, when the moisture

content has been reduced to 39–55 per cent, hand-forked into cars running on tracks through the beds and removed to a dump.

Figures of sludge quantities and analyses are given and comparative experiments with open and glass-covered drying beds are described. A record of Imhoff tank temperatures shows that for 4 months in the year the temperature is low enough to retard digestion considerably. The digestion of Imhoff and activated sludge has been found practicable, and a method is to be adopted by which the waste activated sludge of one works will be added to the fresh sewage entering another works, and the mixed settled solids digested. A machine for removing sludge from the drying beds, developed by the Evers-Sauvage Engineering Company, is described and illustrated. A description of the gas-collecting methods adopted and figures of production are given.—A. H. Goodman and C. E. Wheeler, *Sewage Works J.*, 1: 444, 1929 (papers of Water Pollution Research Board, England).

Report of the Investigation of the Pollution of the Mississippi River, Minneapolis to LaCrosse, Inclusive—This investigation, made in 1928, was confined to the 60-mile section of the river from Minneapolis to LaCrosse, to determine the source, extent, and effect of the pollution, with the view of establishing such requirements as might be found necessary so that this section may no longer be detrimental to the interests affected.

The information obtained permitted the division of this part of the river into four zones:

1. From Minneapolis to Prescott, in which the water is unfit for water supply purposes, bathing, boating, and livestock. In this area nuisances are frequent and fish life practically absent.

2. From Prescott to the head of Lake Pepin,

in which zone some improvement is shown, but the river is unfit for use as a water supply source, or for bathing, and is even dangerous to the health of those coming in contact with it.

3. A zone through Lake Pepin where the water does not comply with standards set for bathing, but in which at certain points the coli-aerogenes content is reduced to where it meets the standards for permissible loading of purification plants.

4. A zone below Lake Pepin where the water appears to have recovered from the effects of the pollution introduced above the lake.

The opinion of the investigating authorities is that the pollution of the river should be restricted so that "the public health hazard will be reduced to a minimum, the live stock will not be materially endangered, the present public nuisance will be eliminated and the fish life in the river, at least below the mouth of the St. Croix, not be jeopardized."

Lead Poisoning from Lead-Piped Water Supplies—Investigations in the industrial clinic of the Massachusetts General Hospital led to the conclusion that non-industrial lead poisoning was a public health problem of importance in districts using lead pipes, especially where soft water was supplied. Investigations showed that the lead content of waters bore a striking relationship to the carbon dioxide content, and that there was little connection between length of pipe and lead content. Figures are given of the incidence of poisoning at different ages and under different conditions.—W. Wright and C. O. Sappington and E. Rantoul, *J. Indust. Hyg.*, 10: 234, 1928 (papers of Water Pollution Research Board, England).

Sewage Treatment in Wisconsin—Public interest in the treatment and disposal of sewage has been steadily developing in Wisconsin, and the Committee on Water Pollution was created in 1927. The state of sewage treatment is graphically presented in a map,

and is shown in a table of the systems adopted. Approximately 55 per cent of the population is served by some form of sewage treatment. The activated sludge plant at Milwaukee serves also 8 surrounding towns and villages. The majority of plants consist only of some form of tank treatment, but recent designs tend toward separate sludge digestion followed by trickling or sand filters. At Hartford and Kiel, Dorr clarifiers and thickeners are used, and at New Holstein a Dorr clarifier with lime precipitation has proved reasonably successful in dealing with pea canneries wastes. Other plants of special interest are referred to. Supervisory, operating and financial difficulties are discussed, and a sewer rental law enacted as a result of the experiences of Ohio and Michigan is quoted. A program of plant inspection and studies to be carried out in coöperation with operators and municipal officials has been adopted by the State Board of Health.—L. F. Warrick, *Sewage Works J.*, 1: 481, 1929 (papers of Water Pollution Research Board, England).

Oil Mixtures and Oil Equipment for Anopheline Larvae Control of Impounded Areas—An impounded area of 7,000 acres in Georgia was controlled by oiling with high pressure spray nozzles operated from boats equipped with outboard motors. Different mixtures of fuel oil and kerosene were first used with poor results. Excellent results were finally obtained by the use of a mixture of 20 per cent black oil (for maintaining the film), 20 per cent kerosene (for toxic effect), and 60 per cent paraffin oil (for spreading). With oil at 11 cents per gallon, the total cost of 22 applications for the season was \$35.00 per acre or \$63.34 per mile of shore line. A list of equipment and detailed costs are presented.—L. M. Clarkson, *South. M. J.*, 22, 4: 397–398 (Apr.), 1929. Abstr. A. W. Fuchs.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Sickness among Industrial Employees—From the summary: 1. Reports from a group of about 35 industrial sick-benefit associations and company relief departments showed that cases of sickness and nonindustrial injuries causing disability for 8 consecutive calendar days or longer occurred at the rate of 103.5 cases annually per 1,000 men during the period 1921 to 1928, inclusive. The rate is considered conservative for various reasons explained in the context.

2. Respiratory diseases were reported as the cause of 42.4 per cent of the cases; digestive diseases, 13.5 per cent; and external causes (nonindustrial accidents), 9.8 per cent. These three groups, accordingly, accounted for nearly 66 per cent of the cases for which sick benefits were paid by associations reporting to the U. S. Public Health Service.

3. In the respiratory group influenza or gripe continues to be of outstanding importance, accounting for 57.5 per cent of the respiratory cases in 1928, compared with 50 per cent during the period 1921 to 1928.

4. The frequency of disability on account of respiratory tuberculosis was lower in 1928 than in any of the preceding years of record.

5. Five of the 9 years covered by the record were marked by influenza epidemics. In the other 4 years the winter incidence of influenza or gripe was of no inconsiderable magnitude.

6. Relatively low sickness rates were found among men employed in the iron and steel industry. An exception was the rate for pneumonia, which appears to be about 50 per cent higher than

among other industrial employees as a whole. Data for a study of the incidence of pneumonia by occupation in the steel industry have been collected and are being analyzed.—Dean K. Brundage, *Pub. Health Rep.*, 45, 3: 107–116 (Jan. 17), 1930.

Physiological Factors of Mine Ventilation—This circular is a very comprehensive summary of recent investigations on silicosis in Australia, Canada, England, Finland, France, Germany, Poland, Scotland, South Africa and the United States. Likewise, a summary is given of recent investigations on abnormal air conditions in mines in relation to high temperatures and humidities and gases found in mines in the various countries named.—R. R. Sayers, *Circular 6196*, U. S. Bur. Mines, Nov., 1929, 17 pp.

Industrial Gas Masks Abroad—This circular discusses the construction of gas masks in general, including the American all-service type with a full-page diagram, and the gas masks used in England, Germany, France and Belgium. The discussion concerns particularly protection from carbon monoxide and also masks used for other poisonous gases, with some details of foreign regulations concerning their use. There are 19 accompanying references.—S. H. Katz, *Circular 6206*, U. S. Bur. Mines, Dec., 1929, 13 pp.

Occupational Diseases, Connecticut—During the month of November, 1929, there were reported 1 case of benzol poisoning, 8 of lead poisoning, 2 of pneumokoniosis, and 17 of dermatitis

and eczema due to the following causes: accelerators, 2; chemical, 1; mercury compound, 12; plating solution, 1; and wood, 1.—*Connecticut Health Bull.*, Dec., 1929, p. 446.

Occupational Diseases Investigated in Massachusetts in 1928—Of the 292 cases of occupational diseases investigated 32 occurred among women. There was one fatality each due to lead poisoning, benzol poisoning, carbon monoxide gas, and one with the cause unstated. Of the total, 123 were due to industrial dermatitis, 41 to lead poisoning, 30 to gas poisoning, 22 to acid and oil fumes, 21 to chrome poisoning, 12 to eczema, 5 to cyanide poisoning, 4 to benzol poisoning, 7 to anthrax infection, 4 to dust inhalation, 1 to tuberculosis, and 16 to other causes.

The industries in which the diseases occurred were as follows: tanneries, 60 cases; textile, 48; mechanical, 38; rubber mills, 24; foundry, 19; metal trades, 13; shoe manufacturing, 10; chemical manufacturing, 9; printing, 5; wood-working establishments, 2; paper mills, 1; mercantile, 1; and miscellaneous, 62.

Investigation of the causes showed in numerous instances that working conditions and equipment were at fault; although the report states that proper measures had been taken for the protection of workers using benzol in different processes in 4 factories, 1 case of poisoning had occurred in each factory. The fatal case occurred in an asbestos textile plant.

Defective or inadequate equipment was found, or employees were not properly safeguarded in other ways even in factories where it was reported that proper measures had been taken for their protection.—Massachusetts Department of Labor and Industry, Division of Industrial Safety, *Report for the year ended Nov. 30, 1928*, pp. 22-31 (abstract from the *Month. Labor Rev.*, 29, 6: 64-66 (Dec.), 1929).

Industrial Partnership—"Industrial Partnership," as designating the modern relationship between employers and employees, is becoming a real working philosophy. This philosophy is a philosophy of management in which the keynote is coöperation, pulling together instead of acting at cross purposes. Good industrial relations have proved to be good business. While it is difficult to find any statistical gauge with which to measure the value of good industrial relations, it is strikingly reflected in the tremendous decline in industrial disputes during recent years. Industrial disputes recorded by the U. S. Department of Labor declined from 3,789 in 1916, to 571 in 1928, or, expressed differently, for every 100 disputes which occurred in 1916 there were only 15 in 1928. This indeed is a significant and encouraging phenomenon to those concerned in furthering the spirit of coöperation between employer and employees and turning what used to be called "the labor problem" into real "industrial partnership."—Brown, Chamber of Commerce of the Borough of Queens, Long Island City, N. Y., NR. No. 255, QCC, 1929.

Conditions of Work in Spin Rooms—A study has been made of the effect of a change of method in the spin room on absence and turnover among women operators in 4 mills from which, however, the results are inconclusive. Another study was made on temperature readings in 15 mills in which it was found that for *dry-bulb* readings, 55 per cent were between 75° and 85° F., with the remainder above 85° five times as often as below 75° and with these high temperatures tending to be emphasized in the northern mills as compared to southern mills. Furthermore, there was a distinct tendency to sustained temperatures of 80° and over without variations of more than 3°, these conditions more noticeable in southern mills. *Wet-*

bulb readings were largely between 70° and 75° F., with southern mills tending to exceed this. Sustained temperatures and lack of variation were both more pronounced in southern mills. As to *relative humidity*, one-fourth of the records were 60 and under 70 (%) in 18.2 per cent of the northern mills and in 33½ per cent of the southern mills, this being within this desirable range; one-fifth of the temperature readings had a relative humidity of 70 (%) or over.—Ethel L. Best, U. S. Women's Bureau, *Bull.* 72, 1929, 41 pp. (tables).

Silicosis Prevention in South African Gold Mines—In the course of the meetings of the British Association in Johannesburg, Professor J. S. Haldane read a paper on July 31, 1929, on the avoidance of silicosis with dry methods of working. Preventive measures underground have consisted largely in laying the dust by wet methods, resulting in a virtually saturated atmosphere which, because of its depth of 7,000 ft. and lower, is also of high temperature, thus rendering muscular effort impossible without grave danger. It was the solution of this problem which was primarily in mind.

Haldane's animal experiments suggested that quartz in shale dust with 60 per cent of total silica did not produce phthisis. "Shafts, inclines, and open levels should be kept dry and stone-dusted with the added dust." Drills should be provided with dust collecting arrangements. Blasting should be so arranged that the dust is scattered over surrounding surfaces with each shot.

Dr. A. J. Orenstein pointed out that the majority of cases of heat strokes occurred among new workers, showing that acclimatization was an important factor, so that it is the practice to put new workers in relatively cool places for a week or two.

Dr. H. Pirow, government mining en-

gineer, sounded a note of warning that the suggestion to use the dangerous silica dust by dry methods might be wrongly interpreted, and the practicability should be investigated before the use of water is restricted.—*Industrial and Labour Information*, 32, 6: 242-243 (Nov. 11), 1929.

The Doctor Looks at Child Labor—The effects on health of child labor are reviewed by 15 specialists, each stating his views according to his specialty, as follows:

Chronic Fatigue, Charles Hendee Smith, M.D.

Hidden Infections, Eugene L. Opie, M.D.

Physical Unfitness, William R. P. Emerson, M.D.

Years of Growth, Haven Emerson, M.D.

Poison Trades, Alice Hamilton, M.D.

Cardiacs without Symptoms, Joseph H. Bainton, M.D.

Colts in Harness, Iago Galdston, M.D.

Monotony Exact its Price, Louis I. Harris, M.D.

Papers! All the Evenin' Papers! Max Seham, M.D.

Young Nomads, Richard A. Bolt, M.D.

When the Hand Slips, Catherine Brannick, M.D.

When Working Conditions are Bad, George M. Kober, M.D.

Undernourished Minds, C. Floyd Haviland, M.D.

—The National Child Labor Association, 215 Fourth Avenue, New York, N. Y., *Publication No.* 356, 1929, 22 pp., ill. Price, 25 cents.

The Dangers of Carbon Monoxide Poisoning and Measures to Lessen These Dangers—This is Report No. 1 of the Committee on Poisonous Gases of the American Medical Association, drafted for the committee by Dr. Yandell Henderson. The other members of the committee are Dr. H. Gideon Wells, Chairman, Dr. Paul Nicholas Leech, Dr. Carey P. McCord, and Dr. L. R. Thompson.

The article reviews the conditions

producing carbon monoxide, asphyxiation by city gas, exhaust gas from automobiles, pollution of air in streets, poisonous action of carbon monoxide, gas masks, resuscitation and inhalational treatment. [The article should be seen in the original by all who are interested. The abstractor's only comments consist in emphasizing the dangers of defective burners on domestic gas fired heating appliances which may in themselves transform a gas containing no carbon monoxide, like natural gas, into one rich in carbon monoxide if the air supply is not properly adjusted to the gas pressure, and to issue a word of warning in testing the quality of an atmosphere by the use of canaries. Some personal experience with canaries in which they were allowed to become gradually acclimatized to an atmosphere which, within 8 hours' time, gradually accumulated carbon monoxide gas from 0 to over 0.5 per cent, failed to more than increase the breathing rate and ruffle the feathers on two canaries so exposed, while 2 white rats were in stupor under the same circumstances. Guinea pigs, however, were not noticeably affected. Undoubtedly, the situation would be entirely different where the canaries are rather rapidly exposed to concentrations of carbon monoxide much lower even than 1 per cent. None of the animals used in the above experiment had had any previous exposure to the gas.]—*J. A. M. A.*, 94, 3: 179-185 (Jan. 18), 1930.

Carbon Monoxide Poisoning in an Automobile—Two strong healthy men were found dead and the driver in a helpless condition in a closed automobile, and the evidence showed that the men had drunk a pint or two of beer, from which the driver was charged with drunkenness while in charge of the car.

Fortunately for the driver, J. S. Hal-dane and Leonard Hill read the report

of the inquest and, seeing that a miscarriage of justice was likely to arise, attended the trial and from evidences which pointed to the peculiar pinkness of the blood bore out the opinion of another physician that death was due to carbon monoxide poisoning.

Hill points out that Dr. Argyll Campbell has found that the injection of alcohol into the veins of rabbits lowers the oxygen tension in the tissue spaces by one-third. The evidence was that while the men had taken a couple of pints of beer, they were sober just before they drove into some water on the road where the car was found. The water was high enough to wet their feet and also to cover the exhaust pipe, so that the fumes escaped into the car. With the engine racing Hill estimated that there may have been 15 per cent of carbon monoxide in the fumes.

The evidence of the police shows that knowledge of the danger of the exhaust fumes of cars and of the fact that poisoning by these produces the same effect as alcohol has not been spread widely enough.—*J. A. M. A.* (London Letter), 94, 2: 116-117 (Jan. 11), 1930.

Benzol Poisoning and Its Prevention in the Rubber Industry—The classifications of the various commercial grades of benzol and a review of its use in the rubber industry are briefly stated. Of the three possible avenues of entrance of benzol into the body—respiratory, alimentary, and skin—only the respiratory is considered of any significance, so far as this industry is concerned. The human system can tolerate very minute amounts over a period of many months if proper aeration and elimination are instituted. Thus an equilibrium may be established between intake and output to this extent.

The chief symptoms of sub-acute and chronic cases and the blood disturbances are briefly listed. "The effects

of benzol are accumulative, more lasting and more severe than those of gasoline." Complete recovery follows exposure to temporary slight concentrations, but it is the constant absorption of small amounts daily that produces the detrimental effects.

The preventive measures comprise: (1) Ventilation and safety devices; (2) the placing of only healthy individuals on operations using either benzol or gasoline; (3) an education program; (4) frequent examinations, especially of the blood; and (5) substitution products for benzol such as high test gasoline, etc. The author's experience has shown that undernourished, anemic individuals, those afflicted with bronchitis, any pulmonary conditions, cardiac or kidney infections should not be employed with either benzol or gasoline fumes present. Likewise, females should not be so employed.

Certain individuals tolerate a large amount of benzol and show very little physical effect. Shallow breathers seem to be less affected. "Alcoholics seem to tolerate benzol or gasoline fumes to a greater extent than others." In benzol exposures workers should be examined every 30 to 90 days (blood, blood pressure, urine, vision, sensory and equilibrium). Where examination shows any indications of absorption the individual is transferred (The Goodyear Tire & Rubber Company).

When admixtures contain carbon tetrachloride to reduce the fire hazard, they should be used only in closed systems of ventilation, due to the extreme nausea and severe vomiting occasioned by the latter substance. "Gasoline works almost as well as benzene in most operations." "It requires very close coöperation between the medical department, the chemical department, safety department and production efficiency department to arrive at a proper conclusion" regarding the use of a substitute product in industry.

Methods of correcting conditions, treatment of the individuals, and a discussion complete the article.—Paul A. Davis, *Ohio State Med. J.*, XXV, 10: 798-801 (Oct.), 1929.

Gas Poisoning—Blood Transfusion—Three telegraph workers were victims of severe carbon monoxide poisoning. Two recovered after blood-letting, lobelin, camphor and inhalation of a combination of oxygen and carbon dioxide gas. The third remained unconscious and his condition got worse and worse; whenever the irritation through the inhalation of the carbon dioxide was discontinued, he ceased to breathe. A transfusion of 400 c.c. of blood resulted in an immediate improvement. Consciousness returned and he recovered completely. "The red blood corpuscles which are introduced evidently assume their function of binding oxygen at once."—Dr. V. Voithenberg, Heidelberg. Abstracted by *Ars Medici* (Oct., 1929, 445) from *Deutsche med. Wchnschr.*, No. 20, 1929.

[The above item should be compared with the following statement taken from *Report No. 1* of the Committee on Poisonous Gases of the American Medical Association, 94, 3: 183 (Jan. 18), 1930, which reads as follows:

Transfusion of blood in cases of carbon monoxide asphyxia, although not harmful, is certainly quite useless. It is performed only when the patient is still unconscious several hours after the asphyxiation. Most of the carbon monoxide, even in a patient not treated by inhalation, has by that time been eliminated from the blood. The continued coma is due to edema of the brain and other post-asphyxial injuries to the nervous system which transfusion of blood does not benefit.]

Chronic Benzene Poisoning Improved by Liver—A Greek-American laborer, aged 38, was admitted to the hospital, November 16, 1928, because of severe bleeding from the gums of 3 weeks' duration, with frequent nose bleed, and spontaneously appearing

black and blue spots on the skin for 2 weeks. During the previous August, he had begun work in an artificial leather shop. Shortly after beginning this work he lost his appetite, felt nauseated at times, and vomited about once a week. At the end of 3 months he noticed itching of the skin and his gums began to bleed. A physician had attempted by various ordinary means (described) to stop the bleeding which followed the removal of two teeth by a dentist, but to no avail. The diagnosis on entering the hospital was puerpera hemorrhagica. On admission the temperature was 101.2° F.; the pulse rate, 96; respiration 24, and the blood pressure was 125 systolic and 80 diastolic. The patient was well developed. There was a vile odor from the mouth. The blood count was as follows: hemoglobin, 62 per cent; red blood cells, 3,300,000; leukocytes, 1,350; polys, 25 per cent;

lymphocytes, 75 per cent; and platelets, 25,000. The bleeding time was 33 minutes.

Three blood transfusions were made at intervals of a few days up to the 10th day, but the blood did not show any improvement. On November 30, 3 days after the third transfusion, half a pound of liver was daily included in the diet. The white count began to show a slight increase on the 3d day, and by the 8th day was 3,900, while bleeding from the gums diminished and was practically absent after December 9. Liver therapy was continued for 7 weeks and the patient kept under observation for 3 weeks longer. In July, 1929, he presented a normal blood picture with the exception of a slight leukopenia of 4,700. He did not resume the liver diet.—Adelaide Ross Smith, *J.A.M.A.*, 93, 25: 1970 (Dec. 21), 1929.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Distribution of Vitamin A in Some Corn-milling Products—This is a qualitative and quantitative study of the distribution of vitamin A in yellow corn in view of the somewhat discordant reports as to the potency of yellow corn in this vitamin. The milling products obtained in the wet-milling process of cornstarch manufacture include starch, corn-germ, corn-germ meal, crude corn oil, grits, gluten, dried steep water, bran (reel slop) and gluten feed. Young rats, 28 to 30 days old, were brought to the condition of ophthalmia by an appropriate vitamin A deficient diet. The food was irradiated and the vitamin B factors were supplied by dried brewers' yeast. The standard rate of

growth for recovery was determined by feeding 8 drops of cod liver oil daily after ophthalmia appeared. Eye symptoms usually developed in 25 to 35 days after the start of the basal diet when various test feeds were added, supplementing the same percentage of starch, or Crisco, or both in the basal diet. Vitamin A value was judged by the minimum dose necessary for the cure of the eyes. Similar amounts, 1.5 gm. daily, of the milling products were fed except in the case of steep water, reel slop and grits, which replaced 50 per cent of the diet. In spite of the comparative high levels of these 3 no reduction in the extent of ophthalmia was observed. Gluten feed in the 1.5 gm.

daily amounts rapidly cured ophthalmia. This is composed of reel slop, grits, steep water and gluten, which indicate all the vitamin A is in the gluten. Since about 10 per cent of the corn is returned as gluten, comparable results should obtain with feeding 0.1 gm. gluten and 1 gm. whole corn; the latter cured ophthalmia but the 0.1 gm. gluten was not sufficient, indicating some loss of vitamin A in the separation. Corn oil, 1.5 to 1.7 gm., slowly cured ophthalmia but the germs and the germ meal even at higher levels were ineffectual. Refined corn oil was found to be deficient in vitamin A owing probably to the result of heating in purification. These experiments show high calcification of vitamin A to be associated with the high pigmentation in corn. The concentration is greatest in the nitrogenous outer layer of the endosperm.—Clara Rocke Meyer and Rossleene Arnold Hetler, *J. Agri. Res.*, 39: 767 (Nov.), 1929.

The Vitamin C Content of Fresh Sauerkraut and Sauerkraut Juice—In spite of a popular belief that sauerkraut is antiscorbutic, two experiments as a result of review of the literature indicate the contrary when sauerkraut is fed at 2.5 and 5 gm. levels to guinea pigs. Two antiscorbutic rations were tried, one, chiefly soy bean flour, and the second, alfalfa, and after demonstrating comparable results the second ration was used throughout the experiment. The protective method was used with young guinea pigs.

The sauerkraut was made from cabbage cut the first week in November, mixed with salt, and allowed to ferment for 90 days at 60 to 65° F. The top sauerkraut was removed and the remainder found of good quality with an acidity of 1.7 per cent as lactic acid. The juice was obtained by pressure from the kraut. In order to induce

better consumption the acidity was half neutralized with normal NaOH. Three levels, 10, 5 and 2.5 gm. sauerkraut, daily were fed. Graphs indicate that the 10-gm. level offered complete protection from scurvy, and there were good gains in weight. This amount appeared to be equivalent in vitamin C to 5 gm. raw stored cabbage. There was no evidence of scurvy in the pigs fed on the 5-gm. level but the average gain is slightly lower than with the higher amount. Out of 6 animals on the 2.5-gm. level daily, only 3 lived through the period. On autopsy there was slight indication of scurvy. The maintenance level of sauerkraut is considered to be 2.5 gm. If 1 gm. raw cabbage is the minimum protective dose this will indicate about one-half vitamin C content destroyed in making sauerkraut. The discordant result of previous investigators whose sauerkraut was obtained from grocery stores is predicated on the possibility of loss of vitamin C by exposure to air in repacking and retailing. Oxidation and not fermentation is the responsible factor. The authors point out that the presence of vitamin C in this experiment will not warrant the assumption that commercial sauerkraut is potent as it reaches the consumer.—Bertha Clow, Abby L. Marlatt, W. H. Peterson and E. A. Martin, *J. Agri. Res.*, 39: 963 (Dec.), 1929.

The Vitamin A Content of Yellow and White-Capped Yellow Dent Corn—Experiments recorded in the literature as well as practical feeding trials have shown the superiority of yellow corn in vitamin A over the white variety. This work was undertaken to determine quantitatively vitamin A in white-capped yellow dent corn. Young rats, 35 to 55 gm. weight, were placed on a vitamin A free diet, modified to include vitamin C, vitamin B complex and vitamin D (through irradiated

cholesterol). In about 5 to 6 weeks the animals were deplete of vitamin A and ophthalmia was in evidence. The corn was ground fine and fed daily except Sunday. Preliminary trials indicated 500 mg. yellow corn per day, and 750 mg. of white-capped corn would result in average gain of 3 gm. per week for 8 weeks. The average net gains for the period were 34 gm. for the white-capped variety and 40 gm. for the yellow variety. The difference between the two means, 6, is less than twice the probable error. This difference is not regarded as significant and the yellow variety is judged to be 50 per cent more potent in vitamin A than the white-capped. The pigmentation of the white-capped variety is less than the yellow but greater than the nonpigmented white variety which has been found very deficient in vitamin A by other workers.—Walter C. Russel, *J. Nutrition*, 2: 265 (Jan.), 1930.

Effect of Liver Diet on Healthy Organism—Neidhardt and Bannasch administered 500 gm. of raw or fried liver daily to eight healthy young men for a period of from 12 to 32 days. At the same time the ingestion of fats was limited and foods rich in vitamins were administered. The ingestion of substances that injure the liver, particularly alcohol, was forbidden and the men were made to lead a regular life and to avoid strenuous bodily exertion. Before the liver diet was begun they were examined clinically and hematologically. The authors noted that even in healthy per-

sons the ingestion of liver produces a definite increase in the number of erythrocytes and a definite but less marked increase in the hemoglobin content of the blood.—*Ztschr. f. klin. Med.*, 111: 147-302 (Sept. 12), 1929. Abstr., *J. A. M. A.*, 94: 71 (Jan. 4), 1930.

Vitamin D Content of the Fat of Marine Mammals—Studies were carried out on rats with the subcutaneous fat of the seal and the dolphin. The seals were obtained from the Caspian Sea and the dolphins from the Black Sea. All of the rats were kept during the experiment in diffused daylight or semi-darkness. After a preexperimental period in which the vitamin D reserves in both the lactating mothers and the young rats were somewhat depleted, a definite rachitic diet was begun and both the prophylactic and curative determinations were made. Experiments indicate that the subcutaneous fat of these animals contains significant amounts of vitamin D, both the curative and prophylactic effects of experimental rickets obtaining with a dose of 0.15 gm. per day, which is equivalent in the case of the seal to 1.4 to 2.1 per cent, and in the case of the dolphin to 1.5 to 2.9 per cent of the food consumed. This compares favorably with the results reported by McCollum and co-workers for good cod liver oil which would demonstrate clearly an anti-rachitic effect in 5 days when in proportion of 1 per cent of the diet.—S. N. Matzko, *Biochem. Ztschr.*, 213, 4-6: 391 (Oct. 8), 1929.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The High Cost of Nursing—In the January *Survey Graphic* which is entirely given over to a discussion of adequate medical care for every man, Janet Geister, R.N., director of the American Nurses' Association, has contributed an article which explains how nurses can adapt their services to middle class needs and purses.

The tradition of providing continuous nursing service to every patient, with a nurse at the bedside 24 hours a day, was established more than half a century ago. Then, with muddy roads and no telephones, doctors were more inaccessible. The physician today has changed from saddlebags to a well-equipped office, but the old practice of continuous nursing still persists. To the average householder, "calling in a nurse" means bringing in the private duty nurse at what he considers an exorbitant cost. And yet the average yearly salary of the private duty nurse is \$1,400.

Every year our visiting nurse associations, which provide bedside nursing to the sick in their homes on a visit basis under the supervision of the family physician, report an increase in their work. The majority of the sick in their homes today do not need continuous nursing care and would suffer no danger under intermittent or hourly nursing. It means waste and cost to nurse the majority of sick patients in their homes on the continuous bedside nursing basis, because the patient pays the private duty nurse for her idle hours with him

as well as for her busy ones, and he cannot pay more than he is now paying. On the other hand, it is the nurse who pays for the time she waits between calls, and she cannot charge the patient less than she is charging.

The problem today is to make it possible for the patient to pay less for skilled nursing care and for the nurse to have a larger and more regular income. If the patient, physician and nurse join hands, why not a broad extension of the principles and methods of visiting nursing? And this means organizing graduate nurse staffs on a salary basis under a bureau or association. The visiting nurse association has already demonstrated how to maintain a high standard of work while distributing nursing service effectively and economically.

Most hourly nursing offered on an organized basis is done by visiting nurse associations or insurance companies. It is done on an appointment basis, and a higher charge is made than for other visiting nursing calls.

To quote from Miss Geister's article:

I believe that the broad extension of the intermittent or hourly nursing principle, designed primarily to bring adequate skilled service to the patient in modest circumstances, is essential if we are to reduce the cost of nursing and at the same time not lower its quality. This extension, however, depends on two major factors: the reëducation of community, doctor and nurse in the use of nursing service; and the development of organized facilities for meeting all types of nursing needs. . . .

Has not the community some responsibility for promoting experiments that will tend to solve one of the cost features in its sickness problem? Can it not discharge this responsibility most effectively at this stage by provid-

ing the capital necessary to finance projects in intermittent nursing until they become self-supporting?—

Janet Geister, R.N., *The High Cost of Nursing*, *Survey Graphic*, Jan., 1930, pp. 426-428.

Industrial Nursing Project—At the fall meeting of the Executive Committee, the director of the National Organization for Public Health Nursing reported on the new industrial nursing project being undertaken with the co-operation of the National Tuberculosis Association.

In the scope of this project the following problems will be included:

1. Preparation of the industrial nurse
2. Content and procedure in an industrial nursing program, with special reference to its relation to the whole industrial health program and industrial management
3. Possibilities of industrial nursing for small plants
4. Relationship of industrial nursing to various phases of the community health program—particularly to the public health nursing organizations

Violet H. Hodgson, an assistant director of the National Organization for Public Health Nursing, is devoting a large part of her time to making contacts in the field with industrial management and industrial nurses in studying this question.

The following have been appointed to compose a special advisory committee for the project: C. O. Sappington, M.D., National Safety Council, Chicago; Alice Hamilton, M.D., Harvard University, Boston; Mary Elderkin, Union Carbide Company, New York,

N. Y.; Eleanor Little, United States Rubber Company, New Haven, Conn.; Elizabeth Fox, R.N., American Red Cross, Washington, D. C.; Volney S. Cheney, M.D., American Association of Industrial Physicians and Surgeons, Chicago; Julia A. Weder, Giant Portland Cement Company, Egypt, Pennsylvania; and Ruth C. Waterbury of the Industrial Nursing Section, National Organization for Public Health Nursing, New York. Kendall Emerson, M.D., of the National Tuberculosis Association, New York, with other representatives of that association, will also sit in on the committee.—Katherine Tucker, Fall Meeting of the National Organization for Public Health Nursing Executive Committee, *Pub. Health Nurse*, XXI, 12: 646 (Dec.), 1929.

Mexico Is Using Visiting Nurses—The Federal Department of Health of Mexico has just decided to undertake an educational campaign to teach child hygiene in the poorer homes by means of visiting nurses. A nurse will remain in each home one or two days or longer if necessary. She will give the mother theoretical and practical instruction in child care, home management, dietetics, and cooking; she will also teach personal hygiene to other members of the family. Follow-up visits will be made regularly to see whether the nurse's instructions are carried out. The corps of nurses necessary for this work is already available, and the work will be started very soon.—*El Universal*, Mexico City, Oct. 15, 1929. I. H.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Slogans in All Languages—Can you get your slogan translated into all the languages spoken in your community, or your state?

You might make the translation job into a contest, giving awards for the most accurate and carefully written translations. Before the awards are announced you might give out the list of languages already represented, asking for other languages actually spoken in your community, or simply invite additions whether or not they are in use in your territory.

How a President Gained and Lost Health—In "Admiral Grayson Lifts the Veil," we are told that

Mr. Wilson was never strong physically. From early youth he had to fight a constant battle for health. The fierceness of this battle was greatly increased by the mental and physical strain under which a President labors. Ever urged on by a sense of public duty, he realized that he must keep physically fit, so that he could carry the burden placed upon him as President. Consequently, he was the best patient a doctor ever had. He carried out my instructions to the letter.

Much against his natural inclination, he regularly took the physical exercise prescribed. He rigorously followed a diet, except in rare instances, when it was necessary for social reasons to depart from it. He slept and worked the number of hours ordered. In fact, his whole life was ordered according to schedule. Under this strict regimen he enjoyed almost perfect health.

Just prior to America's entrance into the war, he said to me: "I am in better health than I have been in forty years." He looked younger and better. His weight increased to 179 pounds. . . . Then came the World War with its added burdens, which was climaxed

by the Peace Conference. When he arrived in Paris, his whole system of living, which we had so carefully built up, had to be changed. He had no time for golf, no time for rest, no time for recreation and exercise, and it was impossible to carry out in hospitable France the rigid diet which he had followed in his own country.

Then is pictured the conditions of life leading to the tragic breakdown. Can health workers use this material?—In *The Home* (Woolworth stores), Jan., 1930.

Free But Not for Free Distribution—A first aim of this department is to make it easy for health workers to get samples of interesting health education materials. And many health agencies are ready to play the game by supplying samples free or for a few cents for postage.

Free after mention of any material means that a sample is free. Very seldom are free copies available in quantities for distribution by other agencies. Why should free copies be supplied? Not even the national agencies have funds for that purpose.

One state department writes:

We are always glad to send sample copies to health workers throughout the country, but frequently are asked to send sufficient numbers for classes which, of course, we cannot do.

Our leading writers of books on health education in schools do much to complicate matters for those who are not prepared to supply free material for the schools. The most widely distributed manual on health education gives dozens of addresses with no clear statement as to what teachers may expect to receive in answer to their requests. Two of the most significant books on health educa-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

tion written by two of our most distinguished and helpful writers confuse matters for teachers who seek helps for classroom work by the nature of the reference lists in those books. Thousands of letters of explanation must be written because three writers of text books were not careful and clear in suggesting sources of information.

Health Was First—The program of the Health Division, National Conference of Social Work, for the meeting in Boston, June 9-14, was the first of the 12 division programs to be complete as to topic and speakers. Congratulations to Chairman Ira V. Hiscock of New Haven, Hawaii and elsewhere.

How Is Your Town?—This question is asked by the American Social Hygiene Association, 370 Seventh Ave., New York, N. Y.

Does your community have laws and ordinances for the prevention of charlatany? Is there a "men's specialist" or a showily advertised "medical institute for blood diseases"? Do posters appear in public places advertising medicines for self-treatment? Does your local paper carry advertisements of the type mentioned? Does your neighborhood drug-store do a thriving business in nostrums?

The association will greatly appreciate any information you may wish to send us on these questions.

A review of "The Charlatan and Venereal Diseases" contains useful background data for anti-quack campaigning. In *Social Hygiene News*, American Social Hygiene Association. Nov. 15, 1929. *Free*.

A reminder of conditions which exist in other cities is "The Exploitation of Poverty, Lowest of All the Rackets." *New York World*. Nov. 29, 1929. Tells of the "Blood Donor," the "Health Inspector," etc.

Statistics of Interest to Newspaper Readers—The following from the Illinois Department of Public

Health might be duplicated with the figures for other states:

Springfield, November 27: Every person in Illinois old enough to read has one chance in a hundred of reaching the age of 90, one chance in ten of arriving at 80 and one chance in three of celebrating his 70th birthday. Furthermore, females have one chance in eight of living to be 80 or more while the male has one chance in twelve of joining the octogenarian club. These conclusions are indicated by the mortality statistics for last year, made public here today by Dr. Andy Hall, state health director, who points out that a considerably larger number of people than formerly are reaching the three score and ten limit in spite of higher death rates among those past 40.

Out of 90,192 people who died in Illinois last year 23,709 were over 70, and 8,333 were less than one year old, Thus more than 35 per cent of the total mortality were included in these age groups. That suggests that people who have survived their first year have at least one chance in three of seeing 70. Last year 25 per cent of all deaths, including infants, were among people past 70 against 24 per cent in 1923 and only 16 per cent in 1918. The effect of the

REPORTING

The 16-page pamphlet, "Signs of the Times: A Brief Resumé of Social Hygiene in 1929," and the accompanying letter from the American Social Hygiene Association, 370 7th Ave., New York, N. Y., is the "report of the month." Copy free. Some of the items to be noted: title, size, paper, marginal statistical references, condensed copy, and letterhead paper. No financial statement.

Did Commissioner Wynne set a new record in health reporting? In exactly one hour after the close of the statistical year of the New York City Department of Health, which ended at 12 noon, December 31, 1929, a summary report was on the Mayor's desk. Explaining the promptness in submitting his report Commissioner Wynne said:

Successful health administration depends on the keeping of all health facts up to the minute. Our statistics are therefore arranged so that we can compile at a moment's notice the health history of the city.

A copy of the 7-page release, which appeared in morning newspapers, Jan. 1st, free.

DIPHTHERIA

The items listed below contain more or less material useful in various forms. A phrase, a paragraph, a statistical comparison, or other element may be utilized in talks, news stories or printed matter. Among the excellent publicity material issued during the past three

years a health officer or executive should find, practically ready-made, the copy and plan for a folder or leaflet to serve his purpose. Why not utilize the good and fine material which has already been worked out?

Diphtheria is the subject of the Nov. 5, 1929, issue of *Chicago's Health*, Dept. of Health.

"Banish Diphtheria," by Shirley W. Wynne, M.D. A readable "day before Thanksgiving" radio talk, with well done historical tie-up. Well worth getting into your files. Free of Health Dept., New York, N. Y.

"Diphtheria Is Preventable" is the new illustrated 4-page folder in color issued by the Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

Diphtheria vs. protection is argued in the Nov. 23 and Dec. 7, 1929, issues of *Weekly Health Review*, Detroit Dept. of Health. Copies free.

In the *Middletown Times-Herald* (N. Y.) for Nov. 14 boxed advertising space announced the Saturday morning toxin-antitoxin clinic of the Health Department. Each box occupied part of the advertising space of a local merchant. A dozen other merchants have promised to do likewise.

The New York State campaign: Oct.-Nov.—scenario prepared for talkie for use in 1930 . . . leaflet prepared for participants in state-wide high school poster contest . . . groups of posters from past contests and selected commercial posters offered to contesting schools . . . Nov.-Dec.—Plans for 1930 campaign reviewed by State Diphtheria Conference Committee. . . . For this 5th year of the 5-year project, effort will be concentrated on the 12 or 15 larger cities of the state.

REGRETTABLE BUT TRUE

A diagram of activities, better than the usual sort, appearing in an annual

report, faces the wrong way so that the reader must change the pamphlet from the left hand to right to be able to look at the diagram.

HONORABLE MENTION

To American Social Hygiene Association: For "Signs of the Times," an outstanding example of a condensed report of varied activities.

To Cincinnati Public Health Federation: For using "Activities of the Public Health Federation" as the cover page title of an annual report.

LETTERS

An original and strikingly effective layout for the two inside pages of a 4-page letterhead came from the New York Tuberculosis and Health Association, 244 Madison Ave., New York, N. Y. The 8 photographs, with brief captions, present as many age or occupational groups which receive health service. The captions illustrate an effective simplicity of style worthy of extended use. "The Chain of Life" on the back page is an attractive idea, but use it somewhere else. As used with other copy, it crowds the fourth page, which would be heavily laden without it. Probably a smoother brand of dull-finished paper would have given better results—less "dirty" looking. Ask for the 1929 Christmas seal letter and enclose 2-cent stamp.

MAGAZINE ARTICLES

See under "Health" in midmonthly issues of *The Survey* for popularly written comment on health problems and activities.

Practically every issue of *Literary Digest* carries several good sized extracts from magazine articles on health topics, and selections from medical journals and public health periodicals.

"Before You Drink a Glass of Milk," by Paul De Kruif. *Ladies' Home Jour-*

nal, Sept., 1929. For discussion of this article see *Health News*, New York State Department of Health, Oct. 21, 1929.

"College Blues," by Karl A. Menninger, M.D. *Survey*. Sept. 1, 1929. Mental hygiene for students.

"How To Prepare For The Winter's Work," by G. F. Alsop, M.D. *Woman's Journal*, 171 Madison Ave., New York, N. Y. Sept., 1929. 25 cents. "For lessening the danger of indoor living."

"If Your Baby Must Be Fed Cow's Milk Be Careful!" by W. R. Ramsey, M.D. *Farmer's Wife*. Oct. 1, 1929.

"Machine Age Adds Quota to List of Medical Fakes." *New York World*. Sept. 29, 1929. "The modern witch doctor's stock in trade."

"The Patient's Dilemma," by Joseph Collins, M.D. *Harpers*. Sept., 1929.

"A Psychiatric Social Worker Looks at Literature," by F. D. Teller. *Survey*. Oct., 1929.

"Stop That Noise!" by Prof. D. A. Laird. *New York World Sunday Magazine*. Oct. 13, 1929. "It is taking unsuspected toll of lives."

"When You Count the Calories, Count the Consequences, Too!" by Dr. W. H. Eddy. *Good Housekeeping*. Aug., 1929. What "every dieter should read."

DATES AHEAD—1930

Mar. 30—Apr. 6—National Negro Health Week. U. S. Public Health Service, Washington, or Tuskegee Institute, Tuskegee Institute, Ala.

April—Early Diagnosis Campaign. See any tuberculosis or kindred association or committee.

April 27—May 3—Better Homes Campaign. Better Homes in America, 1653 Pennsylvania Ave., Washington, D. C.

May 1—May Day and Child Health Day. American Child Health Association, 370 Seventh Ave., New York, N. Y.

Nearly all communities, large or small, will observe one or more of the above. In some cases other health activities will present active participation, but usually local health agencies can get on record their interest and sympathy, and in many cases they can play a prominent part.

GRAPHIC STATISTICS

Has this been used: a diagram of mortality rates illustrated with sketches or silhouettes, on or above the bars or lines, representing individuals at say 1 year, 2-5 years, 6-10, 11-15, 16-20, 21-30, etc.? These illustrations do not represent the rates, but are varied in size only enough to suggest differences in age. *Please tell the editor where you have seen this idea used.*

TRY ONE OF THESE?

A section sliced from a city map, in several colors, is the interest-arousing cover design for an 8-page pamphlet issued by the Regional Plan of New York, 130 East 22d St. *Free.* The pamphlet title appears on a pasted slip $2\frac{3}{4}$ by $1\frac{1}{2}$ inches. A pile of similar maps was cut into sections 13 by $8\frac{1}{2}$ inches, thus providing, when folded once, the cover for a pamphlet $6\frac{1}{2}$ by $8\frac{1}{2}$ inches in size. In making use of the idea care should be taken to select paper and ink for the label to secure contrast with the map background on which it is pasted.

A Buffalo department store has been running a series of advertisements in the form of letters from "Cynthia" to "Dear Dorothy." These letters are rather simple and straightforward in style without any straining after cleverness. Why not write about health in similar fashion?

To advertise your convention: make

up as a handbill—printed only on one side of the paper—reproducing a group of supposed clippings, the copy written in newspaper style, including report that a local board of directors has voted to send delegates; report that delegates have started; reports of meetings and other features of the coming convention, all written up as of yesterday. This device gives opportunity to freshen the trite sayings about convention values and to bring out some of the high lights of the meeting.

A Christmas greeting and a follow-up appeal to buy Christmas Seals—all in imitation penmanship on a postal card—was used by the Denver Tuberculosis Society. *Copy free.*

"Why Sanitary Engineers Are Needed" was the subject of a recent radio talk from the New York State Department of Health. *Copy free.* Various city and state departments describe divisions or bureaus and activities from time to time. Why not check all such efforts in 1929 and note what may have been overlooked?

"DEATH PLAGUE STRIKES THE PLAINFIELDS—Over 4,000 Stricken as Smallpox Threatens . . ."—these are part of headlines from the miniature imitations of the upper halves of two issues of Plainfield (N. J.) *Courier-News*, accompanied by this statement on the cover of a Community Chest folder with a larger page size: "If Plainfield *Courier-News* Carried This Story Tomorrow Millions of Dollars Would Be Raised Over Night!" *Copy for 2 cents.*

LISTS

City health officers—those in cities of 10,000 and up; state and insular health authorities. In *Public Health Reports*, Washington. Nov. 15, 1929. *5 cents.*

BOOKS AND REPORTS

Annals of the Pickett-Thompson Research Laboratory, Vol. V—
London: Baillière, Tindall and Cox,
and Baltimore: Williams & Wilkins,
1929. 392 pp. Price, \$10.00.

This volume, entitled *The Pathogenic Streptococci—Their Rôle in Human and Animal Disease*, includes three monographs. The first treats of streptococci in oral and dental sepsis. A review of publications, as well as the authors' findings, affords ample proof of the important part played by the streptococci in these conditions. They are the most common bacteria found in the healthy mouth. The unique contribution of this monograph lies in its emphasis on the idea that the inadequate methods heretofore employed for identifying these streptococci should be supplemented or replaced by photographic studies of the colonies from direct cultures on Crowe's chocolate agar medium. The authors believe that it is possible to identify with certainty several varieties of streptococci at sight through a stereoscopic microscope. They admit that every given species is capable of considerable colony variation and that the primary colonies of the first isolation may show a difference from those of the first subculture, one of the most variable being *Streptococcus mutans*.

There is no final statement as to the newer suggested methods, but there is a courageous attempt to show progress in a new direction in bringing order out of chaos.

Dentists, doctors and research students will find an excellent résumé of knowledge concerning streptococcal glossitis and stomatitis, dental caries, pyorrhea alveolaris and its treatment by

vaccine therapy, as well as the relation of oral and dental sepsis to rheumatic and cardiac infections and glycosuria.

The second monograph deals with streptococci in tonsillitis and pharyngitis. It is a valuable presentation of the present knowledge of the function, pathology and bacterial flora of the tonsils, as well as the large problem of streptococcal throat infections. It includes a résumé of the work on the effects of tonsillectomy and X-rays, as well as the treatment of tonsillitis, vaccine therapy, carriers, and other related subjects.

The third monograph is concerned with streptococci in puerperal sepsis and septic abortion.

Despite the improvements in surgical technic and the advance of antisepsis, the maternal mortality rate has but little altered during the last decade, and sepsis is still responsible for approximately half the deaths in childbirth (p. 349).

The authors have reviewed the various bacteriological researches into the etiology and sources of puerperal sepsis, and find:

... the evidence is overwhelming that acute puerperal sepsis is almost invariably caused by streptococci.

The literature on the use of vaccine and serum therapy shows that the results not only vary but are disappointing, though not unfavorable, the best results being obtained from the use of autogenous streptococcal vaccines. Literature on chemo-therapy in puerperal fever is well presented.

There are about 1,150 references to literature, and 46 plates of excellent photographs of colonies and organisms.

The volume will prove an incitant to careful thought and research on the

three important phases of disease here presented. With the preceding volumes, it constitutes the most extensive study of the streptococci yet published, and is indispensable to bacteriologists.

ESTHER W. STEARN

Aids to Zoology—By Harry Lister.

New York: Wood, 1929. 214 pp., 29 figs. Price, \$1.50.

This is a condensed handbook of the structure and life histories of a series of animal types with a brief account of histology, embryology and evolution. It includes a number of parasitic species.

C. A. KOFOID

Epidemic Encephalitis. Etiology, Epidemiology, Treatment—Report of a Survey by the Matheson Commission. New York: Columbia University Press, 1929. Distributed by Dr. William John Matheson and the Matheson Commission on Encephalitis Research, 706 W. 168th St., New York, N. Y.

Few diseases have excited more interest during the past 10 years, and none have been more puzzling than encephalitis. The profession generally will therefore welcome this study, which has been made under the direction of a commission financed by Dr. William John Matheson, and carried out under the direction of Dr. Josephine B. Neal, who has not only made a thorough survey of the literature, but has visited many parts of Europe where personal interviews with those best informed on the subject were held, and studies of patients as well as pathological specimens conducted. The names of those consulted in this country as well as Europe are convincing evidence of the authoritative character of the testimony collected.

One hundred and five pages are given to etiology, 30 to "other types" of encephalitis, 42 to treatment, and 222 to epidemiology. The rest of the book—

with the exception of a good index—some 428 pages, is given to a well arranged bibliography.

Too much cannot be said of the excellent character of this study, not only in design, but in the way in which it has been carried out and is now presented. One is inclined at first to be disappointed at the lack of conclusions, but certainly nowhere else is there to be found such a collection of information concerning this obscure disease. The commission has rightly felt that a knowledge of the facts is the foundation on which future work must rest. It would be arrogant for the average reviewer to draw conclusions when the commission and its director have not seen fit to do so.

In the foreword, we are told that at the suggestion of Dr. Matheson, the commission is continuing the work, and has undertaken a number of studies on causes, treatment and results; so we can look forward confidently to further contributions which will doubtless add greatly to our knowledge and which, we trust, will allow of conclusions useful to the average practitioner.

The present volume being a collection of facts and figures, does not lend itself readily to review, though it is of great value to all interested in the subject.

The chapter on Etiology gives us the stages through which the pathological investigations have passed; that on epidemiology gives a section to practically every country in the world, and includes age, sex, and seasonal distribution. The cases reported from England and Wales exceed those of any other country by some 5,000.

The work so far is deserving only of the highest praise. The medical profession particularly, but also the public, who are the sufferers from the disease, owe a debt of gratitude to Dr. Matheson, who has financed this endeavor, as well as to the commission which has the work in charge, and especially to Dr.

Neal, who has not only directed the work, but personally carried out most of it.

The printing and make-up of the book are excellent. M. P. RAVENEL

Backgrounds of Biology—By John Giesen and Thomas L. Malumphy. Milwaukee: Bruce, 1929. 278 pp., 66 figs. Price, \$2.50.

This is a textbook of elementary biology prepared by teachers in Holy Cross College. It is diagrammatic in its presentation of its facts and in places dogmatic in its assertions of the limitations and inadequacy of many current biological hypotheses including, for example, Darwinism, the tropism theory of Loeb, and eugenics. Orthodox biologists will find it interesting reading. There are excellent chapters on infection and immunity. C. A. KOFORD

The Blood Picture and Its Clinical Significance (Including Tropical Medicine)—By Prof. Dr. Victor Schilling. Translated and edited by R. B. H. Gradwohl, M.D. (7th and 8th ed. rev.) St. Louis: Mosby, 1929. 408 pp. 44 ill. Price, \$10.00.

This book portrays indeed the advance made in practical hematology, being unique in composition and of much importance to laboratory investigators and internists, who are interested in the subject.

The first part deals with the technic of blood examination, introducing a new blood test called Guttadiaphot. Part two comprises the theory, morphology and division of the blood picture. The hemogram, which is an outstanding feature, and Arne's qualitative blood theory are discussed. Part three gives the principles for clinical use of the blood picture, while part four, being a supplementary addition, gives selected examples, demonstrating the practical use of the hemograms.

The author emphasizes the fact that

the cases described are particularly clear cases, selected from very vast material, and that a study of the blood picture is useful even in the simplest cases, since it reinforces the physician's judgment by simple confirmation, or strengthens it in a symptomatic and prognostic manner.

The cases are illustrated by "hemograms," a method devised by the author. A simple classification of the polymorphonuclears is used. The simplicity of the method is very practical and its use should be encouraged. The work is replete with information and very well written. There is a full bibliography of the German literature appended.

ALBERT G. BOWER

The Commonwealth Fund Activities in Austria. A Record of Collaboration for Child Health, 1923-1929—By William J. French, M.D., and Geddes Smith. New York: Commonwealth Fund Division of Publications, 1929. 131 pp.

This is an unusually attractive report. It is a record of collaboration, for, as stated in the foreword, the Fund has in no instance endeavored to superimpose its own ideas or methods of health work upon the different Austrian communities to which it has given assistance. Health work is not in a rudimentary stage in Austria, and the Fund has endeavored to make possible a development of the program originating from the Austrians themselves or given a local or national color by them. "American initiative has been needed only to help in clearing the way for a thoroughly Austrian enterprise." The Austrians have their own ideas as to what ought to be done and how it should be done; and for the carrying out of a program they bring "their keen enthusiasms, their native pride, their courtesy and wit, their cheerful poverty, their fears for the future of Austria, and their power to dissociate themselves from their fears and throw

themselves without reservation into the task at hand."

The second guiding principle of the Fund was to limit itself to such lines of activity as it felt would meet the most outstanding need, and render the greatest public service. While the main purpose of the report is to record projects taken up, and accomplishments in the health program, some of its most enlightening features are the sketches presenting the historical background of the nation and of each of the six provinces and districts to which assistance was given.

The starting point for improvement and expansion in many instances was the school health program or an attempt to correlate and improve child health work already being done by a number of agencies. The commendable reductions made in preventable diseases, particularly among children, as well as the result of some specific measures such as the prevention of simple goiter in Vorarlberg, are clearly indicated.

The important rôle of the midwife in Austria, in contrast with her receding place in America, is set forth; also the contrast between the type of midwife of a few years ago and the one now doing service in Austria. The activities and influence of the home visitor (Fürsorgerin) in Austria are among the most important factors in carrying the benefits of public health to a community. There seems to be no public health worker in America whose functions cover the range of services rendered by this Austrian home visitor.

The report indicates that the future of child health work in Austria is hopeful. "The direction of public health effort to all appearances is firmly fixed; it is the same as that of enlightened governments everywhere. Austria has grave doubts of her future as a nation, but she is determined to safeguard the future of her children."

The report is well written, pleasing to the eye, easily read, and contains 20

exceptionally fine illustrations which add to the attractiveness of the report and supplement the text. JAMES WALLACE

Second Annual Report of the Metropolitan Drainage Commission of Minneapolis and St. Paul.

In 1927 the Minnesota legislature created the Metropolitan Drainage Commission to study the subject of sewage disposal in the area of Minneapolis and St. Paul. This, the second annual report of this commission, contains its opinions that:

1. The cities of Minneapolis and St. Paul should unite to form a single district for the treatment and disposal of sewage.
2. South St. Paul and Newport should be left out of the district at the present time but should be permitted to contract with it for the disposal of their sewage and wastes.
3. The project for the treatment of all sewage in a single plant in the Pig's Eye Lake district should be adopted, provided equitable financial adjustments of the costs of the intercepting sewers can be made.
4. This conclusion pertains to fixing the annual tax rates in the two cities so as to make them as nearly uniform and equitable during the period of construction as possible.

The report is too long to go into thoroughly, but its preparation warrants its careful review. One striking feature is the finished charts, of which there are 154. These are clear and elucidating and make the report much more readable.

Six plant sites and 20 treatment projects were studied and from a careful comparison of these the conclusion in favor of the Pig's Eye Lake one was drawn. This project utilizes a system of medium level interceptors which will deliver the sewage to the vicinity of Pig's Eye Lake. About 1,000 acres of land are available and the site is suitable for digestion tanks and drying beds, as a large part of it is remote from dwellings. The project permits the construction of either an activated sludge plant or a trickling filter type and provides for complete treatment in 1970.

ARTHUR P. MILLER

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

United States Public Health Service—The fifty-eighth annual report of the Surgeon General of the U. S. Public Health Service covers the 131st year of its existence. During the fiscal year 1929 there was a constant interchange of sanitary information with other nations through the International Office of Public Hygiene of Paris, the Pan American Sanitary Bureau, and the health section of the secretariat of the League of Nations. Mortality was not so low as in the two previous years when unusually low records were attained. Furthermore, an influenza epidemic, although more mild than in 1920 and 1918–1919, reached a large number of countries.

Meningococcus meningitis was unusually prevalent in the United States during the latter half of 1928 and the early part of 1929. More cases were reported than for any year since 1918. This disease was prevalent in Chinese ports during 1929 and in April and May caused more than the normal number of deaths in England and Wales, Scotland, Germany, and Italy. Typhoid fever and relapsing fever declined and the trend of cholera in India was downward. Yellow fever was reported in Brazil, a severe outbreak occurring in Rio de Janeiro.

In the United States, a birth rate of 19.7, a death rate of 12.1, and an infant mortality rate of 67 are recorded for 1928. There were 38,000 cases of smallpox reported.

It seems strange that year after year more cases of smallpox are reported in the United States than in any other country of the world except British India. Yet this disease can be controlled by vaccination and revaccination, and with the coöperation of the public could be stamped out in the course of a few years.

A reduction of 86 per cent in the

death rate from typhoid fever during the last century, to a rate of 4.8 per 100,000 population, has been brought about largely through the practical application of the principles of modern sanitary science.

The figures show not only the saving of about 47,000 lives in one year, but the avoidance of an incalculable amount of human suffering and economic waste.

In 1928 the death rate from tuberculosis in 42 states was 77.5, the lowest ever recorded, and comparing with a 1900 rate in the death registration area of more than 200.

No instance of the importation of any quarantinable disease occurred during the year. The preventive measures applied by U. S. Public Health Service officers at foreign ports of departure are reflected by the small number of quarantinable diseases on vessels arriving at United States ports.

In spite of preventive measures, and of the decrease in prevalence of venereal diseases which must have taken place since the World War, it is estimated from extensive studies that there are constantly under treatment or observation by physicians and clinics in the United States approximately 474,000 cases of gonorrhea and 643,000 cases of syphilis. It is also estimated that 697,000 cases of gonorrhea and 422,000 cases of syphilis seek treatment for new infections in the course of a year. The Service has continued its efforts to reduce the prevalence of venereal diseases, through coöperation with state and local health authorities, the carrying on of educational work, and the conducting of research in problems related to the treatment and control of syphilis and gonorrhea.

An impressive list of investigations of public health problems is contained in

the report, including among others cancer studies, milk investigations, trachoma, stream pollution, malaria, industrial hygiene, child hygiene, goiter, nutritional diseases, and undulant fever. An extensive volume of coöperative work was conducted by the Service during the year, including practically all the departments and certain of the independent establishments of the government.

Rosenwald Fund—This annual review for the year ending June 30, 1929, presents not only the major activities of the Fund but includes an enlightening discussion of the underlying principles of modern philanthropy. Consideration is given to Negro welfare as a program deserving national support; and to the need of pay clinics and other forms of organized medical services for the general population.

The most extensive group of activities of the Fund during the year was co-operation with southern states and counties in building public schools for Negroes. Assistance has also been given to the development of colored public health nursing work, to proper housing facilities, to the extension of library services, and to the study of various medical problems, including the Cost of Medical Care.

Cleveland, O.—The 1928 report of the health division opens with a map showing the health districts of the city and the location of district stations. This map serves to orient the reader. A general mortality rate of 10.27 is recorded on the basis of an estimated population of 1,010,300. A resident birth rate of 14.99 in 1928 compares with a rate of 23.1 in 1920. Births in hospitals to resident mothers have increased during this period from 22 per cent to 44 per cent.

Tuberculosis statistics are analyzed extensively by districts. A death rate

of 85.9 (75.2 pulmonary) in 1928 compares with a rate of 128 (109.8 pulmonary) for the year 1913. A total of 1,688 new cases of pulmonary tuberculosis was reported, and less than 10 per cent of the fatal cases had not been reported before death. During the year there were 263 fatal automobile accidents. Responsibility for these accidents was chargeable to drivers in 43 per cent of the cases, to adult pedestrians in 31 per cent of the cases and to children in 21 per cent of the cases. Over half of the report is devoted to detailed statistical tables.

Anderson County, S. C.—This county with a population of 85,000 maintains a health unit consisting of a medical director, a nurse, a clerk and a sanitary inspector. Antityphoid campaigns were directed during the year in sections of greatest prevalence, and 10,824 inoculations were given in clinics. A toxin-antitoxin program undertaken in the fall of 1928 resulted in the immunization of 3,656 children. There were only 2 deaths from diphtheria in 1929.

A Kiwanis clinic for crippled children was held at the county health unit offices. Of 49 children examined, 21 were selected for orthopedic correction. One day each week is devoted to well baby conferences. A goiter survey of high school pupils showed that endemic goiter is not a problem in the county. The health unit maintained a booth at the county fair and featured the "milky way" and the power gained from the use of milk as a food. Some 50,000 pieces of health literature were distributed there.

Cincinnati Public Health Federation—Opening with lists of coördinating committee members and organizations represented, the 1928 health federation report of 52 pages contains much interesting information regarding the work of this voluntary agency. Be-

sides the President's report are accounts by the chairmen of councils on cancer control, child hygiene, clinics and dispensaries, day nurseries, heart control, housing, mental hygiene, mouth hygiene, nursing, social hygiene and tuberculosis.

According to an excellent chart of the Federation, each council is made up of the professional and lay people interested, and meets monthly. A council on health education has recently been formed. It is gratifying to note that the President of the Academy of Medicine has announced a plan to encourage physicians to perfect themselves in making physical examinations, and that the Federation will coöperate by urging the public to consult competent physicians for an annual check-up.

New Jersey—A popular review of health activities of the State Health Department for the year ending June 30, 1929, is contained in the September-October *Public Health News*. The control of physical connections between public potable water supplies and other unapproved supplies was secured by a new act of the State Sanitary Code. This regulation prohibited new cross connections and required that those in use be equipped with all bronze double check valves of an approved type if they are to be retained. Such check valves are allowed only on yearly permit, which must be approved by the local board of health, the local water department and by the State Department of Health.

The state-wide diphtheria prevention campaign was continued and resulted in the immunization of over 125,000 children at public clinics. During the previous year approximately 133,000 children received similar treatments. Public offers of toxin-antitoxin or toxoid treatments were made by 290 of the 556 cities, boroughs and townships in the state up to the first of the year 1929. Among the important factors in this campaign have been the program

of education and the clinic demonstrations carried on by state and local health officials for several years, and the active participation in the campaign last year by the New Jersey Committee for the Prevention of Diphtheria.

It is stated that the education and the direction of the work of midwives, which has been carried out in the state for many years, has resulted in fewer midwives and in greatly improved standards of practice and equipment. In the last 10 years, the proportion of total births attended by midwives has decreased from 42.2 per cent in 1918 to 18.1 per cent in 1928. Only 4 per cent of the puerperal deaths were among mothers attended by midwives.

The annual courses offered jointly by Rutgers University and the State Department of Health for the professional education of persons engaged in public health work in New Jersey were attended last year by 42 health officials. At the 2-weeks intensive course for sewage plant operators, held in midwinter, 19 students were given laboratory experience and lectures on sewage treatment practice and theory.

The summer courses for health officers, inspectors and nurses, which began in June, gave practical instruction to 23 employees of local boards of health or of other organizations in New Jersey.

New Haven, Conn.—The 1928 report of the department of health opens with an organization chart showing the various bureaus, staff and total budget, in addition to coöperating organizations, voluntary and official. This city with a population of 187,867 reports a resident death rate of 10.3 and a birth rate of 16.2, with an infant mortality rate, corrected for residence, of 53.4 and a tuberculosis rate of 54.3.

Early in the year, exposure to 5 cases of smallpox, one of which was a resident, stimulated an active vaccination cam-

paign. Twelve vaccination clinics were established and the manufacturing and commercial groups coöperated. During a period of a few weeks, over 100,000 people were vaccinated, including 10,000 school children. During the year there were 170 cases of smallpox in the state of Connecticut with but a single case in the City of New Haven.

There were 6 deaths from diphtheria, the largest number since 1923, when toxin-antitoxin immunization work was

undertaken. There were no deaths from typhoid or scarlet fever. Over 4,000 children, including 1,900 pre-school children, were given 3 immunization doses against diphtheria. There are now some 40,000 considered as protected against this disease. An outstanding feature of the report is a careful analysis of the problem of tuberculosis and a comprehensive report of the tuberculosis bureau, which will be of interest to health officers.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Immunizing Cows against Tuberculosis—Swiss cows were treated experimentally with "Friedmann's Bovine Medicine" (the Friedmann of turtle bacillus notoriety) and with BCG vaccine. Post-mortem findings "do not permit the conclusion that Friedmann's medicine had unfailing preventive power." But clinical examination of the vaccinated (BCG) animals seemed to indicate increased resistance against tuberculosis.

BAER, H. Immunization against Bovine Tuberculosis with BCG and Friedmann's Vaccines in the Canton of Zurich, Switzerland. *J. State Med.*, 38, 1: 48 (Jan.), 1930.

Irradiated Ergosterol—Cod liver oil alone prevented or cured rickets in nearly as high a percentage of children as did the oil plus irradiated ergosterol. The latter alone in equivalent dosage was not so efficient as the plain cod liver oil.

BARNES, D. J., *et al.* The Comparative Value of Irradiated Ergosterol and Cod Liver Oil as a Prophylactic Antirachitic Agent When Given in Equivalent Dosage According to Rat Units of Vitamin D. *Am. J. Dis. Child.*, 39, 1: 45 (Jan.), 1930.

Changing Death Causes—Massachusetts mortality statistics are presented to show the changing trends through three decades. The analysis provides texts for a hundred health sermons.

BIGELOW, G. H., and HAMBLIN, A. Changing Causes of Deaths. *New Eng. J. Med.*, 202, 5: 215 (Jan. 30), 1930.

Industrial Sickness Rates—Illnesses lasting more than a week are

compiled from 35 industrial sick benefit associations. The average annual rate is 103.5 per 1,000. Respiratory diseases caused over 42 per cent of cases. Other valuable statistical findings are deduced.

BRUNDAGE, D. K. Sickness among Industrial Employees. *Pub. Health Rep.*, 45, 3: 107 (Jan. 17), 1930.

Industrial Health—The sanitarian's opportunity to individualize his health program through industrial hygiene is set forth.

CANNON, O. A. Health Opportunities in Industry. *Canad. Pub. Health J.*, 21, 1: 1 (Jan.), 1930.

Isolating Tubercle Bacilli—Oxalic acid, 5 per cent, instead of sulphuric acid, 6 per cent, is suggested for isolating bacilli from sputum because it is less toxic for tubercle bacilli and has a greater germicidal effect upon contaminants.

CORPER, H. J., and UYEI, N. Oxalic Acid as a Reagent for Isolating Tubercle Bacilli and a Study of the Growth of Acid-Fast Non-pathogens on Different Media with Their Reaction to Chemical Reagents. *J. Lab. & Clin. Med.*, 15, 4: 348 (Jan.), 1930.

Food Handler's Examinations—Eight years' experience in examining food handlers in the city of Newark (N. J.) is reported in an excellent paper by the Health Officer of that city whose matured opinion is that it is well worth while and that such examinations have come to stay.

CRASTER, C. V. The Medical Examination of Food Handlers. *Pub. Health (Great Britain)*, 43, 4: 102 (Jan.), 1930.

Health Education Through Biology—An "all sustaining motive," not found in the fear of disease, must be the basis of all health education. The author finds it in a biological setting. It is to be regretted that this stimulating paper is not reprinted in an American publication where our own health educators might see it.

HALL, J. Health Education. *J. Roy. San. Inst.*, 50, 7: 450 (Jan.), 1930.

Hemorrhagic Diphtheria in Canada—This story of 70 cases of fatal diphtheria may prove useful ammunition for health workers who are stimulating the general use of toxin-antitoxin.

HANNAH, B. Hemorrhagic Diphtheria. *Canad. Pub. Health J.*, 21, 1: 9 (Jan.), 1930.

Carbon Monoxide Poisoning—A committee report which finds that educational measures to prevent carbon monoxide poisoning are valuable but insufficient. Preventive regulations are suggested. Recommendations for the resuscitation of victims are also included.

HENDERSON, Y. The Dangers of Carbon Monoxide Poisoning and Measures to Lessen These Dangers. *J. A. M. A.*, 94, 3: 179 (Jan. 18), 1930.

Worth-while Annual Reports—What should be included in health reports and how it should be presented is the theme of this all too short paper for New Jersey health officers. The message is as badly needed in every other state of the Union. It should be widely read.

HISCOCK, I. V. The Purposes, Contents and Preparation of Health Reports. *Pub. Health News (N. J.)*, 15, 1: 4 (Dec.), 1929.

Diet for Underweight Adults—Will cod liver oil and milk, when supplementing the diet of underweight adults, decrease "colds," increase body weight, improve efficiency, correct abnormal physical conditions? The an-

swer of this demonstration is: yes, in part.

HOLMES, A. D., *et al.* The Economic Value of Cod Liver Oil and Milk as Dietary Supplements for Underweight Adults. *New England J. Med.*, 202, 5: 225 (Jan. 30), 1930.

Smallpox Experience in Holland—A sailor coming from a Dutch colony in the Indies brought alastrim (mild smallpox) with him. The disease spread, assuming a graver aspect and causing some deaths among people who had never been vaccinated or who had been vaccinated many years before.

JITTA, N. M. J. The Smallpox (Alastrim) Epidemic in Holland. *Pub. Health Rep.*, 45, 2: 66 (Jan. 10), 1930.

BCG Status—The pros and cons of this lively controversy seemed to be presented impartially. BCG gives protection, but it is too early to decide how much. It may be not without danger; hence the general use cannot be recommended. Even scientific people find it difficult to examine a cold subject of fact objectively and without bias, concludes the author.

KLEINSCHMIDT, H. E. What Is the Status of BCG? *T. Nurse & Hosp. Rev.*, 83, 6: 805 (Dec.), 1929.

Water-borne Disease on Ships—An interesting account of a typhoid fever outbreak among passengers on a lake steamer due probably to by-passing polluted water about the drinking water still.

MENDELSON, I. W., *et al.* Water-Borne Disease Epidemics on Ships. *J. Am. Water Works A.*, 21, 12: 1660 (Dec.), 1929.

Canadian Health Legislation—This brief statement of the history of health legislation in a Canadian province presents some interesting contrasts in public attitude toward health promotion.

RIDDELL, W. R. Health Legislation in the Province. *Canada Lancet*, 74, 1: 13 (Jan.), 1930.

Anorexia in Childhood—Health workers will be most interested in this paper and the discussion following it because of the warning against following blindly "the quart of milk a day" slogan in the case of anorexic children. A warning that deserves general reading.

SCHULTZ, F. W. The Problem of Chronic Anorexia in Childhood. *J. A. M. A.*, 94, 2: 73 (Jan. 11), 1930.

Financing County Health Work—Subsidy from extra-county sources is justified. How the aid shall be allotted and apportioned is the subject of an interesting study.

SIBLEY, E., and MOUNTIN, J. W. Apportionment of Financial Aid for County Health Work. *Pub. Health Rep.*, 45, 1: 1 (Jan. 3), 1930.

Tularemia Up-to-date—Recent additions to our information about tularemia, here and abroad, introduces a report on new cases.

SIMPSON, W. M. Recent Developments in Tularemia. *J. Lab. & Clin. Med.*, 15, 4: 311 (Jan.), 1930.

Estimating Antineuritic Potency—A diet capable of producing polyneuritis in rats allows the determination of minimum curative doses of vitamin B concentrates when injected intravenously.

SMITH, M. I. A New Method of Evaluating the Potency of Antineuritic Concentrates. *Pub. Health Rep.*, 45, 3: 116 (Jan. 17), 1930.

Physical Impairment in Adults—The findings of 9,000 physicians making uniform examinations of 100,000 men constitute a valuable picture of physical conditions. These papers are the first of a series of statistical studies.

A summary presented in excellent graphs appears in January number of the Milbank Memorial Fund Quarterly Bulletin.

SYDENSTRICKER, E., and BRITTEN, R. H. The Physical Impairments of Adult Life. (Two papers.) *Am. J. Hyg.*, 11, 1: 73 (Jan.), 1930.

Hemolytic Streptococci—Streptococci isolated from typical cases of scarlet fever, erysipelas and septic sore throat cannot by any method now available be separated into specific groups—not a comforting conclusion for those who talk glibly about *streptococcus scarlatinae*, *erysipelatus*, and *epidemicus*.

WHEELER, M. W. Streptococci from Cases of Epidemic Sore Throat, Scarlet Fever and Erysipelas. *J. Prev. Med.*, 4, 1: 1 (Jan.), 1930.

Human Relations Institute—This is one of the few lucid accounts of the growth and aims of the Yale Institute of Human Relations. Health workers will be interested in the possibilities in this promising project.

WINTERNITZ, M. C. The Institute of Human Relations at Yale. *New England J. Med.*, 202, 2: 58 (Jan. 9), 1930.

Smallpox Statistics—Case reports of smallpox for the states and island possessions of the United States, and the provinces of Canada are assembled for comparative purposes. The ready reference may be of use to those who wish to discuss vaccination.

WOODWARD, S. B. An Argument in Favor of Vaccination, with Statistics of the Incidence of Smallpox in the United States, Its Dependencies and Canada. *New England J. Med.*, 202, 3: 122 (Jan. 16), 1930.

NEWS FROM THE FIELD

NEW YORK HEALTH COMMISSIONER RESIGNS TO BECOME COUNTY HEALTH OFFICER

MATTHIAS Nicoll, Jr., M.D., Fellow of the A. P. H. A., who has been Commissioner of Health of New York State since 1923, resigned on January 16, to become Health Officer of Westchester County at the same salary, \$12,000.

In presenting his resignation to the Governor, Dr. Nicoll gave as one of his chief reasons, "an ambition to organize a county health department on a scale which may ultimately serve as an example not only to other counties of New York but to those of other states."

The first official act of Dr. Nicoll after taking the oath of office as Health Officer of Westchester County was to appoint Richard Slee, M.D., District State Health Officer, as his deputy, at a salary of \$7,000, and William A. Holla, M.D., second deputy, at a salary of \$6,000.

Some of the other positions which are to be filled are: sanitary engineer, \$4,000; veterinarian, \$3,500; supervisor of public health nurses, \$4,000; 4 public health nurses at \$2,100 each, and a statistician, \$3,000. For the first year's expenses the County Board of Supervisors appropriated \$50,000, which the state will duplicate, making the total appropriation \$100,000.

Dr. Nicoll's association with public health activities in New York State dates back to 1908 when he became chief of the Division of Diagnosis in the New York City Department of Health, of which Hermann M. Biggs, M.D., was Chief Medical Officer. Dr. Biggs, who became State Commissioner of Health in 1914, appointed Dr. Nicoll

director of the Division of Public Health Education, December, 1915. He was made Secretary in 1916, Deputy Commissioner in 1917, and on the death of Dr. Biggs in 1923 succeeded him as Commissioner.

MATTHIAS NICOLL, JR., M.D.

Some of the outstanding features of Dr. Nicoll's administration are the close understanding with the medical profession which has been established through his efforts; diphtheria prevention work resulting in much lower morbidity and mortality rates from this disease and the lowest recorded rates in 1929; the promotion of prenatal and child hygiene work; the persistent efforts which have been made to prevent or overcome stream pollution by sewage; and the securing of the purification of a large number of water supplies.

Dr. Nicoll's action serves to emphasize in a striking manner the importance

of the county as the political unit best fitted to administer local public health work.

At the time this article was written, no successor to Dr. Nicoll had been announced by Governor Roosevelt. Dr. Paul B. Brooks, Deputy Commissioner under Dr. Nicoll, is acting health commissioner.

THE RAVENEL AWARD IN PUBLIC HEALTH

THERE has been established at the Medical College of the State of South Carolina The Ravenel Award in Public Health, for which Dr. Mazýck P. Ravenel, Professor of Bacteriology and Preventive Medicine, University of Missouri, will annually give a silver cup as the prize. The award has been established as a memorial to those of the name who have advanced science in Charleston and South Carolina, and those who have been connected with the college in the past. This cup will be awarded annually to the student doing the best work in public health during his attendance at the college, providing that the work is of sufficient merit.

The first award will be made at the commencement June 5, 1930, at which time Dr. Ravenel will give the Commencement Address.

VIRGINIA PUBLIC HEALTH ASSOCIATION

A MEETING of the Association was held in Richmond, January 9, 1930. The principal speakers from outside were Homer N. Calver, Executive Secretary of the American Public Health Association, who talked on The Functions of a State Health Association, and Blanche M. Haines, M.D., of the U. S. Children's Bureau, who gave an interesting talk on Presidential Interest in Child Health. Charles R. Grandy, M.D., President, and J. Allison Hodges, M.D., President-Elect of the Medical Society of Virginia, spoke on Coöperation between the Physician and the Health Worker.

W. Brownley Foster, M.D., President of the Association, gave an interesting paper on Negro Mortality as his Presidential Address. Papers were also read by C. L. Outland, M.D., L. E. Sutton, Jr., M.D., and Fred J. Wampler, M.D.

New officers elected for the year were: B. B. Bagby, M.D., of Courtland, President; P. M. Chichester, M.D., of Clarendon, 1st Vice-president; and L. J. Roper, M.D., of Portsmouth, 2d Vice-president. Fred J. Wampler, M.D., remains Secretary-Treasurer. Rowena Kneebone, of Richmond, was elected assistant Secretary-Treasurer. Dr. Wampler was elected the Association's representative on the Governing Council of the American Public Health Association.

HONG KONG SEEKS TO STOP THE SELLING OF GIRL CHILDREN

AN ordinance has been introduced into the legislative council of Hong Kong which seeks to abolish the system by which parents or natural guardians can sell their daughters into other households to what is frequently a condition of practical slavery. The proposed law forbids such transfer of a minor under the age of 18 except for the *bona fide* purpose of a proposed marriage or adoption according to the Chinese custom, and it also makes it an offense to possess a girl illegally transferred after the coming into force of the ordinance. A law for the protection of the "mui-tsai," as these girls are called, was passed many years ago, but no machinery exists by which it is possible always to make certain whether girls are mui-tsai or not, and the law has remained largely a dead letter.

ARIZONA PUBLIC HEALTH ASSOCIATION MEETING

The Arizona Public Health Association will hold its Third Annual Meeting in Phoenix, Ariz., April 15 and 16. A program of interest to health officers,

public health nurses, and sanitary engineers is being arranged. Details of the program can be secured from the Secretary of the Association, Jane H. Rider, State Department of Health Laboratory, Tucson, Ariz.

31,500 KILLED BY MOTORS IN 31 STATES IN 1929

FIGURES made public on January 15, 1930, by the National Safety Council showed 31,500 persons were killed in automobile accidents in 31 states during 1929.

The total was 13 per cent more than in 1928, the report said, while motor vehicle registration increased only 8 per cent.

California fatalities increased 20 per cent on the basis of a 9 months' comparable period, and New York and Ohio had 17 per cent increase on the basis of an 11 months' comparable period. Oregon, Rhode Island, Delaware, Wisconsin and Vermont show slight decreases in the first 11 months.

More than half the victims were pedestrians.

RENT ALLOWANCES FOR CHILDREN, GREAT BRITAIN

THE National Housing and Town Planning Council of England has suggested that a rebate on the rent of the minimum standard municipal houses should be made in the case of families with three or more children having a maximum weekly income of 55s (about \$13). The English post-war housing schemes have greatly benefited the better paid workers, but they have not emptied the slums because rents for the new municipal houses are too high for the poorer families.

STANDARDIZATION OF TERM "BLINDNESS"

DIFFICULTIES are encountered in attempting to arrive at a total figure for the blind population of the

world, the Health Organization of the League of Nations explains; only a rough estimate can be made, especially in view of the fact that no general agreement prevails as to the exact condition which constitutes blindness. A very conservative figure of 2,390,000 is quoted as a "probable under-estimate" made in 1910, together with the statement that other estimates have been made up to 6,000,000. In those countries where a census of the blind cannot be obtained, it is said, the prevalence of blindness is frequently great.

CANCER RESEARCH FUND

ANNOUNCEMENT that the cancer research fund of the Graduate School of Medicine of the University of Pennsylvania has received an anonymous gift of \$210,000 was made recently by Dr. Josiah H. Penniman, provost of the university.

The gift is the largest single contribution to the cancer research fund, which was established in 1928 through a gift made by Irene du Pont. It has enabled the fund to reorganize its work on a wider and more comprehensive basis and to make notable additions to its research staff.

CHILD WELFARE MEASURES IN ITALY

IN accordance with instructions from the Minister of the Interior of Italy all the prefects throughout the Kingdom have recently called the attention of the mayors and the local health authorities to the need of strict enforcement of the school hygiene regulations. The prefects point out, among other things, the need of talks on the following subjects: Hygiene for the school children, the teachers, and the parents; the keeping of individual health records for the children; and thorough cleanliness of the school rooms. The local health officers are required to visit the schools at least once a month to enforce the sanitary regulations.

COST OF MEDICAL CARE UNDER SICKNESS
INSURANCE IN GERMANY

IN 1928, the sickness insurance funds of Germany, which take care of cases of illness lasting not more than 26 weeks, spent nearly 203,000,000 Reichsmark (\$48,355,000) on the medical care of non-insured wives and dependent children of insured persons. Of this amount nearly 13,000,000 Reichsmark (\$3,097,000) were spent on dental treatment alone. The cost of the medical care of the 20,000,000 persons insured by these funds amounted to nearly 1,500,000,000 Reichsmark (\$357,300,000). The expenditures of the funds have been steadily increasing.

PRIZE OFFERED TO ITALIAN PHYSICIANS

THE Royal Society of Hygiene of Milan has offered a prize of 5,000 lire (\$260) to Italian physicians for the best manual on the physical and mental health of children between the ages of 8 and 15 years. The manual must deal with all subjects relative to the development of the child. Some of the subjects to be discussed are food, clothing, physical and mental training, recreation, problems of sex life, vocational training and guidance, and character education.

It must be written in simple language, suitable for the use of parents, teachers, and other persons dealing with children.

CONNECTICUT DIVISION OF MENTAL
HYGIENE

THE Division of Mental Hygiene of the Connecticut State Department of Health has been put on a full-time basis under the direction of Dr. McCartney. It is believed that this is the first state department of health to establish a full-time division on mental hygiene.

DR. NICOLL HONORARY LIFE MEMBER OF
STATE AND PROVINCIAL HEALTH
AUTHORITIES

On January 15, Dr. Matthias Nicoll, Jr., former New York State Commissioner of Health, became an honorary life member of the Conference of State and Provincial Health Authorities of North America under a by-law of the organization which provides that ex-presidents of the Conference on the date of retirement from their official positions as state, territorial or provincial health officers shall automatically become honorary life members.

PERSONALS

ANNIE W. GOODRICH, Dean of the Yale School of Nursing, sailed for the Orient recently to study nursing conditions in the Far East for the Rockefeller Foundation.

DR. HUGH H. SHAW, Health Officer of Utica, N. Y., was recently reappointed to that position by the Mayor.

C. J. DURKEE, Assistant Director of the Division of Public Health Education of New York State, resigned her position recently.

DR. THEOBALD SMITH, formerly Director of the Laboratories of the Massachusetts State Department of Health, has been appointed consultant in Bac-

teriology of the Division of Laboratories and Research of the New York State Health Department.

DR. JAMES EWING, Professor of Pathology at Cornell University Medical School, is the consulting pathologist of the laboratories of the New York State Health Department.

DR. DON M. QUIRK, Health Officer of Watkins Glen and Dix, N. Y., died recently, after a long illness.

DR. SANFORD R. GIFFORD, Omaha, Neb., has been appointed head of the department of ophthalmology at Northwestern University School of Medicine, Chicago, Ill.

MARTHA D. RING, formerly assistant editor of the *International Critical Tables*, has been appointed editor of the Committee on the Cost of Medical Care.

MACENNIS MOORE, publicity director, Wisconsin Anti-Tuberculosis Association, has become publicity secretary of Seattle Community Fund.

VINCENT Y. BOWDITCH, M.D., formerly president of the National Tuberculosis Association, died in Boston, Mass., December 21.

HARRY B. ANDERSON, of the U. S. Public Health Service Hygienic Laboratory at Washington, D. C., died on February 8 of psittacosis, contracted while working with infected parrots.

DR. WALTER W. LEE, formerly of the Indiana State Board of Health, has been appointed Epidemiologist of the Connecticut State Department of Health.

DR. ROBERT F. SEIBERT of New Britain has been appointed Assistant Epidemiologist of the Connecticut State Department of Health.

WILLIAM ROYAL STOKES, M.D., Fellow of the A. P. H. A., of the Bureau of Bacteriology of Baltimore, Md., died on February 10, in Baltimore, of psittacosis.

DR. FRED WILLIAM BROWNING, Health Officer of Hayward, Calif., for almost a quarter of a century, died December 30.

CONFERENCES

Apr. 15-16, Arizona Public Health Association, Phoenix, Ariz.

May 5-10, First International Congress on Mental Hygiene, Washington, D. C.

June 6-14, National Conference of Social Work, Boston, Mass.

June 12-14, Western Branch of American Public Health Association, Salt Lake City, Utah

June 18-19, State and Provincial Health Authorities of North America, Washington, D. C.

June 20-21, Conference of the Surgeon General, Washington, D. C.

FOREIGN

May 19-21, Second International Malaria Congress, Algiers, Algeria

June 4-9, Congress of Royal Institute of Public Health, Portsmouth, England

June 21-28, Royal Sanitary Institute, 41st Congress and Health Exhibition, Margate, England

Aug. 3-9, Second International Congress for Sex Research, London, England

Aug. 4-9, International Veterinary Congress, London, England

Established Points in a Community Program of Health Education*

The Health Department's Program

HENRY F. VAUGHAN, D. P. H., F. A. P. H. A.

Commissioner of Health, Detroit, Mich.

THE American Public Health Association in preparing its *Appraisal Forms* for city and rural health work has endeavored to create a measuring stick which incorporates, in terms of group judgment, established points in a communal program of health education. A very important section of the *Appraisal Form* is devoted to popular health instruction in which tangible means of measuring the quantity and the effectiveness of recognized implements of health instruction have been incorporated.

The use of pamphlets, lectures, talks and motion pictures, as well as publicity through daily and weekly newspapers and the publication of bulletins and periodic reports giving account of the activities of the health department and special demonstrations aiming to promote the cause of public health, have all been given numerical value with the view of offering a comparison of the intensity of the educational program in various communities. A further perusal of this same *Appraisal Form* will indicate that throughout the text, in sections devoted to other recognized divisions of health administration, further numerical value is given to methods of procedure which might be placed under the caption "health instruction." The graphic presentation of death rates, the publication of statistical reports, and the use of spot maps and chronological charts, are the invaluable tools of the health educator, and constitute the very foundation stone for the vital statistician and the epidemiologist. The section of the *Appraisal Form* dealing

* Read before the Public Health Education Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

with the health of the school child includes features of health education in the schoolroom and the section on sanitation gives tangible value to the instruction of food handlers.

In addition to these well defined uses of the printed page and courses of instruction dedicated to such specific projects as the supervision of food handlers, we must not overlook the most widely accepted factor in the community program of health education—the public health nurse. The effectiveness of the nursing work is measured on the appraisal yardstick by the degree to which the public responds, as evidenced by the attendance at tuberculosis and venereal disease clinics, the frequency with which the mother avails herself of prenatal instruction, and later takes her child to the infant and pre-school clinics. All of these established features of a properly organized health education program are now generally recognized and accepted by the health administrator throughout the land. It is not the purpose of this paper to refer in detail to these implements of education so admirably evaluated by this Association, but rather to discuss certain aspects of the mechanics for the application of these generally recognized principles.

It is one of the prime functions of a health officer, either by himself or through his organized department, to keep the public informed regarding the activities of his organization. This can best be done through the medium of the newspaper by describing in readable and understandable English those routine services which affect the common citizen in his daily life. There is no universal prescription; individuality and personality will vary the pictorial presentation. The people of one city may demand the sensational and unusual. The health officer is never justified in sacrificing the accepted and proven facts of health for the sensational and startling portrayals of unproven and doubtful origin. He is most successful who can mix the dry language and statistics of the scientist with the highly colored portrayals of the modern commercial advertiser.

Many health administrators have worked out a coöperative arrangement with newspaper editors whereby an article describing some feature of the health department's activities is accepted at least once a week. Such article may appear either as a news item or as a special contribution under the name of the author, or as a feature story for the Sunday edition. Pictures are invaluable in reaching the reader.

Too many annual reports of purely statistical character are published by health departments. For the most part they are wasteful of paper. Very few individuals read the details. It seems to be a tradition among health officers to publish a report which may contain

a short introduction by the administrator, but which consists largely of disjointed, poorly prepared and inadequately presented departmental reports. How much better to present a logically yet simply told story of the activities for the past year, giving only the high lights of statistical importance, such as the total death and birth rates and the death rates from the more important causes. The annual report may well be an account of the activities of each of the divisions and sub-divisions of the department, told in an informal and coherent fashion and not as a formal, choppy and jumbled statement from the director of this or that division. Preferably the same author should prepare the entire report, or at least one individual should serve as editor so that phraseology and method will be consistent.

Another important function of the health department is to keep the public informed concerning the prevalence of disease and the possible influence of epidemics on the health of the local community. A weekly bulletin printed by the health department or merely released and published by the newspaper will serve this purpose admirably. It is needless to state that such releases should be made to all papers whether printed in English or foreign languages. In case of epidemic the public should be informed daily of the facts. Health as a news feature has always received due consideration from the newspaper editor. The reader is especially interested in knowing the means of disease prevention and relief in time of epidemic.

It is understood that all health departments do not perform the same services although there is a background common to all. If some of these services, such as centers for maternal, child hygiene and pre-school guidance, tuberculosis and social hygiene are under the supervision of nonofficial agencies, the obligation of the latter in keeping the public informed concerning their activities is as real as would be the responsibility of the health officer were they under his direction. In most instances the nonofficial agencies serve to supplement the official health organization or serve as units of demonstration to convince the public of the need of some particular activity. So far as the communal health program is concerned, both the official and the nonofficial should be considered as a single unit.

The most important task of the health department in developing a health education program is not to take care of the unusual situation which develops during an epidemic period; it is not to describe the mechanics of operating a department or even to notify the public of the prevalence of the various communicable diseases; but rather to build up a system whereby a health consciousness will become established in the mind of each citizen.

After eliminating the multitude of local variables such as climate, race, nativity, color, age, etc., we believe that the death rate from any specific preventable disease reflects the degree to which popular health instruction has stimulated a response on the part of the individual members of the community group and found reflection in the application of the principles of personal hygiene and healthy living. After making the necessary statistical corrections and allowing for abnormal local influences which may result in a more liberal policy with respect to the hospitalization and care of cases at public expense, the tuberculosis death rate may be taken as an index of the local health consciousness with respect to tuberculosis prevention; that is, of the intelligence and learning of the average citizen with respect to the known facts concerning the cure and prevention of this particular disease.

What is true of tuberculosis is likewise true of other communicable diseases such as typhoid fever, diphtheria and scarlet fever. It is especially true of the infant death rate, which serves as an admirable index of the end results of health education in the conservation of child life.

It should therefore be an objective of the health officer to stimulate this condition of health consciousness so that by degrees the citizen automatically incorporates into his daily habits the practice of personal hygiene, and secures for himself and his family the specific means of stimulating artificial protection against such diseases as diphtheria and smallpox. The methods of the commercial advertiser which the medical quacks and charlatans have used so profitably in their business may well be utilized by the health officer. As previously stated, sensationalism should not be utilized at the expense of truth, but a modernistic tendency in the presentation of simple facts will do much to stimulate response from the laymen. The educational program should be built on the best known scientific foundations.

Why not use the successful methods of the commercial advertiser? When an automobile manufacturer is ready to present a new model to the consuming public, he tells the advertising house which handles his account that he has four-wheel brakes, a non-shatterable wind-shield, an automatic lubricating system, demountable tires, etc. The commercial advertiser then builds his story about these new features. He does not have to resort to his imagination but has these new improvements in automotive engineering to offer the public. Throughout his advertising scheme there is a continuity of program—a catchword or phrase which the public learns to associate with his product, such as "Ask the Man Who Owns One," or, "When Better Automobiles are Built, ——— Will Build Them." The automobile manufacturer is

not alone in this field of advertising; it has been adopted for every type of product with such captions as "Not a Cough in a Carload," and "That Schoolgirl Complexion."

Health officers with their academic and professional limitations have made beginnings but much remains to be accomplished. The aptly coined phrase of Biggs: "Public Health is purchasable; within reasonable limits any community can determine its own death rate," has seen wide usage but has not had the personal appeal that has accompanied the undertakings of commercial enterprises.

What has the health officer to sell? For the prenatal case, there is a physical examination with pelvic measurements and a periodic urinalysis; for the mother and child, a safe confinement under hospital conditions, with well trained personnel in attendance; for the infant, supervision of the milk and food, proper rest, suitable clothing, sun-baths, avoidance of excesses. Later there is the period for vaccination against smallpox and immunization against diphtheria. By the time of the first birthday the periodic medical examination should become an accepted fact to be continued through the preschool and school periods, accompanied by the correction of physical defects.

If the health officer could go to the commercial advertiser and present not a new motor car with self-lubricating devices and non-shatterable glass, but a service for the expectant mother, immunization against diphtheria, vaccination against smallpox, the periodic physical examination, great advance could be made in carrying to the parents, and especially the mothers, a consciousness of the fact that they are responsible for the health of their children, and that the application of preventive measures early in life will do much to reduce a high infant death rate and to ward off the communicable diseases so prevalent in the preschool group.

All material of a medical character used in such an educational program should, of course, have the approval of the properly organized medical society. There should be no tendency toward paternalism. The state or city should not perform services which belong rightfully to the parent, except in so far as demonstration is needed and the relief of indigency is compelled.

Attempts have been made in this direction with notable success, although in some instances there has been a tendency to substitute standardized prescriptions for the individual attention of the practicing physician. In our judgment this is a mistake. The condition should never arise whereby reference to a guidebook becomes a substitute for a physical examination at the hands of the family physician—rather should the educational program prove the value of his service.

There should be a continuity of program throughout the entire story, closely interwoven with the personal service and demonstration offered by the public health nurse, for whom the printed page can never serve as a substitute.

The machinery through which such an educational program can be put into effect is variable. There are marriage statistics which afford one means of approach to the prenatal case. There are the birth certificates which give a ready and immediate contact with the mother of the new-born child. Literature delivered by the public health nurse with a word of explanation will obtain better results than when sent through the mail.

We are not endeavoring to mention all the ingenuous methods which have been or may be employed in making contacts in a given field. Suffice it to say that the possibilities are large and, though brave beginnings have been made, no well planned modernistic instruction combining the resources of the public health nurse and the printed page has been consummated. As the nearest approach to what we have in mind we might cite the splendid program inaugurated by Herman N. Bundesen, M.D., as Health Commissioner of Chicago. Doubtless his word did much to stimulate a health consciousness on the part of the people in Chicago and if so it will find reflection in a lowered morbidity and mortality rate for that city.

Let us again repeat that the official and nonofficial agencies must supplement each other in their program of health education. The facts to be presented must be built upon the knowledge which comes to the health officer largely through his division of vital statistics supplemented by research and epidemiological study. The art of modern advertising remains still to be applied in the public health field.

Medical Care of School Children in Hesse, Germany

A VERY thorough system of medical care of elementary school and continuation school children has been recently introduced by a Government decree in the State of Hesse. Each pupil must be given a physical examination at the time of entering school; at least once during his school career; and again at the time of graduation, when he is also given vocational advice. In addition, the school physician must also make a less thorough inspection of every child once a year.

The local authorities are ordered to introduce dental care in every school, if possible. Children whose physical condition is not very satisfactory are to be examined at regular intervals to be determined by the school physician. Individual health records are to be kept. The school physician will be assisted in the work by school nurses or welfare workers.—*Deutsche Ztschr. f. Wohlfahrtspflege*, Berlin, Dec., 1929, p. 597.

Water Treatment With Chlorinated Copperas*

A. CLINTON DECKER, F. A. P. H. A., AND H. G. MENKE

Sanitary Engineer, Tennessee Coal, Iron and Railroad Company, Birmingham, Ala.; and Assistant Sanitary Engineer, State Board of Health, Montgomery, Ala.

DURING January, 1928, it was decided by the Chickasaw Utilities Company and the Alabama Water Service Company to install additional facilities at the Water Works Plant at Chickasaw, Ala. These additions were to include equipment to afford full treatment for color removal, clarification and disinfection.

The Chickasaw Plant is owned by the Chickasaw Utilities Company, a subsidiary of the United States Steel Corporation, and was leased early in 1928 to the Alabama Water Service Company to supply water to the towns of Chickasaw and Pritchard. Chickasaw was built by the United States Steel Corporation during the war to provide housing for the employees of the Chickasaw Shipbuilding Company, a subsidiary of the Corporation. It is about seven miles north of Mobile and has a population of about 2,000. It is un-incorporated. Pritchard, with a population of about 1,500, is about one mile from Chickasaw, and is incorporated.

At the time Chickasaw was built the water works system constructed was large enough to supply the domestic and fire protection requirements of the village and plant.

Investigations of possible sources of supply included wells and surface water. Due to the chemical content of the well water and the large number of wells required, it was decided to use Eight Mile Creek. This stream originates in springs and flows through a heavily cypress wooded territory, which imparts a color ranging from 40 to 130 p.p.m. The turbidity normally varies from 3 to 25, and on very rare occasions reaches 50. The alkalinity ranges from 2 to 5 p.p.m., and constitutes the total hardness. The pH varies from 5.5 to 5.9. The bacterial content is unusually low for surface water, the count being mostly under 100 per c.c. at 37½° C.

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

The original treatment consisted of sedimentation and chlorination. The sedimentation basin was composed of two units, each having a capacity of 500,000 gal., into which water was pumped with a low lift pump. From this it was lifted to the 200,000 gal.-elevated steel storage tank, being chlorinated as it entered the high lift pump. The high lift pumping equipment consisted of one 1,200 gal. per minute and one 2,000 gal. per minute pump.

After the decision to provide full treatment, including color removal, at this plant, the method of treatment had to be determined. The interested companies, in coöperation with the State Board of Health, undertook experiments to determine the best method. The first experimental work was done in February and April, 1928, and consisted of both bottle experiments and the operation of an experimental filter. The latter consisted of barrel containers and orifice boxes for chemical dosing, mixing trough, coagulating basin, and filter. Water was siphoned from the sedimentation basin and mixed with the chemicals by means of a sloping herring-bone baffled trough. The coagulating basin was of plain lumber—roughly 3 ft. 4 in. x 6 ft. in plan and 6 ft. deep. This was divided into 3 compartments by round-the-end baffles. The filter was constructed from an ordinary hot water tank which gave it a surface of exactly 1 sq. ft. The rate of filtration was controlled by an adjustable hose through raising or lowering the discharge end.

The whole plant was designed to secure maximum flexibility in regard to time of mixing and chemical dosage. We used ferrous sulphate, alum, lime, and soda ash in various quantities and combinations. It was our opinion that the best results of coagulation and color removal were obtained when 3 gr. per gal. of lime and $5\frac{1}{2}$ gr. per gal. of alum were used. The raw water showed an alkalinity of 2, color 22, turbidity 3, and pH 6.0; the filtered an alkalinity of 8, color 0, turbidity 0, and pH 6.4. On the basis of these findings, it was concluded that a treatment plant could be operated satisfactorily and at a reasonable cost.

Plans were prepared in accordance with recommendations made as a result of the above experiments, and construction work was begun the first week in January, 1929. After the plant had been designed, the possibility of the use of chlorinated-copperas was brought to our attention by L. H. Enslow, Research Engineer of the Chlorine Institute. This, however, did not necessitate any change in the plans except in the chemical equipment.

Laboratory scale experiments preceded the plant scale demonstration made early in April, 1929, and both gave excellent color removal.

The best results were secured by employing 0.7 gr. per gal. of copperas previously oxidized by adding the amount of chlorine theoretically required to oxidize the ferrous iron (1.5 p.p.m.) and, in addition, sufficient to satisfy the chlorine demand of the raw water, making the total application 2.16 p.p.m. At the end of the mixing chamber 0.2 p.p.m. of residual chlorine was present in the coagulated water. Thus, copperas oxidation and prechlorination was effected simultaneously. In passage through the basins, however, the residual chlorine disappeared and the water going on the filters contained none. It was noted that 0.4 gr. per gal. of sodium aluminate was used in conjunction with chlorinated-copperas the floc was somewhat more feathery in appearance and settled more rapidly than that produced by chlorinated-copperas alone.

There was no appreciable difference in the amount of color removal with either of the above methods of coagulation. When sodium aluminate was used, it was introduced in the third compartment of the mixing chamber, theoretically $3\frac{1}{2}$ minutes after the introduction of the chlorinated-copperas. Coagulation was readily obtained with various dosages of chlorinated-copperas, or with chlorinated-copperas and sodium aluminate. However, the color removal was the factor in determining the minimum dosage, and although coagulation could be obtained with smaller dosage, color removal was not complete except with the amount stated. At times, when the floc seemed to be shrinking in size, our first point of investigation was the mixing barrel where the chlorine was being added to the copperas solution. Usually, upon applying the ferricyanide test for the presence of ferrous iron in the copperas-chlorine mixture leaving the barrel, the blue color was produced, indicating incomplete oxidation of the copperas. Because of this, the chlorine dosage was increased to 2.16 p.p.m. to insure an excess at all times, and likewise provide the prechlorination dosage desired.

Chlorinated-copperas^{1,2} is prepared by mixing a solution of ferrous sulphate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$) commonly known to the trade as "copperas" and chlorine water from a chlorinator. The copperas may be fed from a dry feed machine into a solution box, or be made into solution in a tank and fed through orifice boxes. The function of the chlorine is to oxidize the ferrous iron before the solution reaches the raw water. It is evident that the same feed equipment employed for other coagulants is useful with chlorinated-copperas, the only addition being the chlorination equipment.

Provision had been made for introducing lime at various points in the last bay of the coagulating basin and also into the clear well. At

FIGURE I—Chemical Feed Machines

different times, lime was introduced at about 130 ft. and 50 ft. from the filters, and into the clear water well immediately adjacent to the filter effluent pipes. When lime was introduced into the coagulating basin, the final quality of water was not so satisfactory as when it was put into the clear water well. There was a slight increase in color in the latter case, but it was not so great in the finished water as when the lime was introduced into the coagulating basin. In all cases, lime sufficient to adjust the pH up to 7.0 or 7.2 was used. The alkalinity was raised to 7 or 8 p.p.m. The final color averaged about 3 p.p.m., and never exceeded 5. The effluent in regard to color and brilliance was eminently satisfactory. The appearance of the water was impaired when enough lime was added to correct the pH to the desired point of 7.4; i.e., the increase of color intensity was very noticeable when the pH was corrected to values above 7.2. On this account, the final water was left at pH between 7.0 and 7.2. At

FIGURE II—Chemical Feed Machines

times since, the lime application to the filtered water has produced a pH value of 8.0 without serious color increase.

When it had been determined that chlorinated-copperas could be used, the equipment selected was Wallace and Tiernan Type "B" Dry Feed Machines, and Type "M. S. V." Chlorinator (see Figures I and II). No mixing device had been provided for chlorinating the copperas, so when the plant was put into operation, it was necessary to improvise one. A 50-gal. barrel was placed on a bracket immediately adjacent to the first compartment of the mixing chamber. The copperas solution line from the dry feed machine was cut and so arranged as to lead into this barrel, discharging at the bottom, causing a swirling action in the barrel. An outlet pipe from the barrel into the mixing chamber was taken off at the top. Chlorine was introduced through the chlorinator discharge hose at a point near the bottom. The swirling action caused an intimate mixture of the two chemicals and secured the oxidation of the copperas (Figure III).

Complete oxidation of the copperas is the essential part of this process, and in the construction and operation of a plant using "chlorinated-copperas," care and special attention should be devoted to a design which will secure this result. During the operation of the plant, frequent tests should be made to determine that complete oxidation is being obtained. In the design of plants using this treatment the box in which the copperas and chlorine are mixed should be easily accessible for taking samples for the oxidation test. Samples were collected frequently from the chlorinating barrel discharge, and

FIGURE III—Barrel in which Copperas is Chlorinated

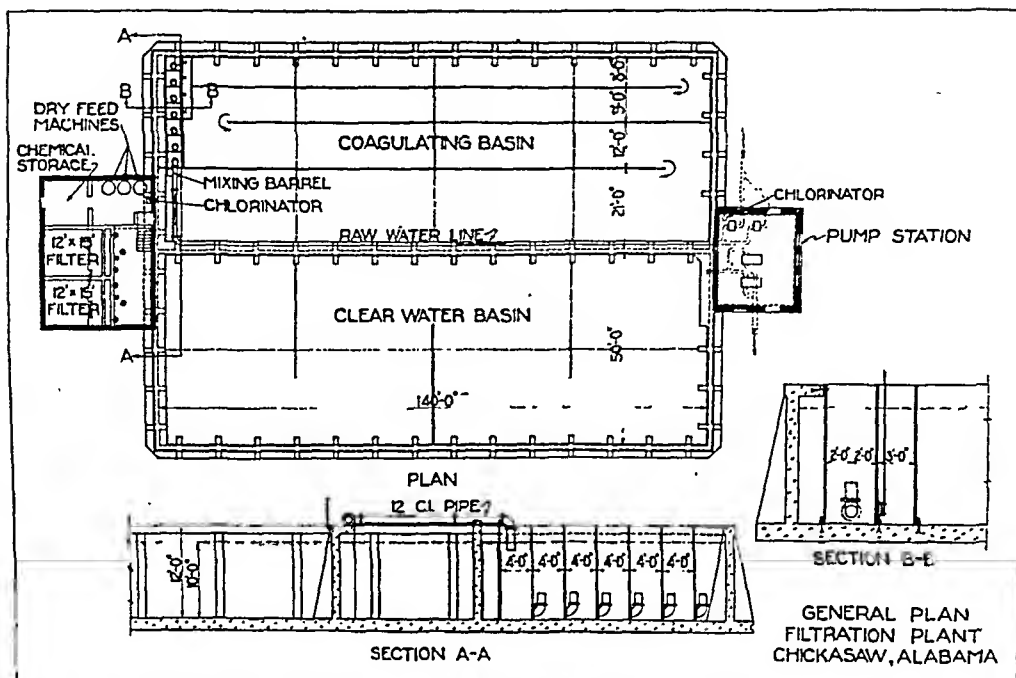

FIGURE IV

the test applied until there was assurance that the copperas-chlorine ratio was being properly maintained and no ferrous iron was being discharged. It is, as already pointed out, far preferable to operate on the side of safety and always have present some excess chlorine, than to err in the other direction.

The mixing chamber and coagulating basin were adjusted to one unit of the original settling basin. The mixing chamber consists of a series of vertical compartments through which the water passes. There were seven compartments, each 4 ft. square in plan and extending to full depth of the coagulating basin, 10 ft. The raw water is introduced over the top of the first of these compartments in a downward direction, leaving at the bottom through a 12 in., 90° bend, and a nipple 18 in. long, and working upward through the second compartment. Each succeeding compartment is piped in the same manner. Water is thus introduced into each compartment with an upward motion and must travel a distance theoretically equal to twice the depth of the compartment. Arrangements were made so that the water could leave the mixing device from any of the compartments, commencing with the fourth. This provided flexibility in operation and allowed the mixing period to be varied in accordance with the water being treated. The water from the mixing chamber entered a stilling chamber, after which it was introduced into the first bay of the coagulating basin, which was divided into four bays by three round-the-

end baffles. These baffles were set to produce theoretical velocities as follows:

First bay.....	1.165 ft. per minute
Second bay.....	1.035 ft. per minute
Third bay.....	0.778 ft. per minute
Fourth bay.....	0.445 ft. per minute

With this arrangement, it was hoped to effect a more even distribution of the sludge (Figures IV, V and VI).

Water was taken from the last bay by a 700-gal. per-min. Allis-Chalmers 750 r.p.m. centrifugal pump. The pumping of the coagulated water was made necessary to adjust new work to old, and on account of the topography and character of the soil. The filters were of concrete with perforated pipe collecting system. Each was of $\frac{1}{2}$ million gal. per day capacity.

Water from the filter was discharged into the clear water basin through a 10-in. cast iron line. This clear well is the other half of the original plain sedimentation basin. The clear water well has been baffled with three transverse round-the-end baffles to secure, as nearly as possible, complete displacement and prevent dead water. The suction line of the high duty pump is at the opposite end of the basin from the filter effluent pipe. The chlorine is introduced into the suction pipe of the high duty pump.

FIGURE V—Coagulating Basin and Filter Building

We would emphasize the fact that complete oxidation of the copperas is absolutely essential to the success of this method of coagulation and that a small excess of chlorine is desirable. An efficient mixing device for chlorinating the copperas should be provided. Substantially complete color removal can be accomplished on waters of the character of that being treated at the plant described, using 0.7 gr. per gal. of chlorinated-copperas. Correction can be made with lime to adjust the pH up to 7.2 without materially impairing the color. Increasing the pH value above 7.2 intensifies the residual color.

The process is efficient and economical without being unduly tedious. Continuously satisfactory results have been obtained during the 6 months that the plant has been in operation. The saving in cost of chemicals as compared with that of other processes tried was found to be very substantial—in our case amounting roughly to \$10.00 per million gallons.

A Survey Schedule for Industrial Hygiene

THE Committee on Administrative Practice, from the beginning of its work, felt the need of including within the scope and detail of its local surveys information with respect to the industrial health service of communities. Some time ago a committee was appointed by the Chairman of the Committee on Administrative Practice, consisting of W. S. Rankin, M.D., Chairman, Prof. Leonard Greenburg, Secretary, V. S. Cheney, M.D., E. R. Hayhurst, M.D., A. J. Lanza, M.D., E. M. Price, F. L. Rector, M.D., W. A. Sawyer, M.D., and L. A. Shoudy, M.D. This committee was asked to recommend supplemental information to that called for on the regular survey schedule of the Committee on Administrative Practice, so that sound advice as to the industrial health services of communities might be provided for.

It was clearly understood that the sub-committee would not attempt to set up a system for evaluating or appraising the industrial hygiene service of a city, but would limit its work to the preparation of a schedule of information for obtaining additional and special information not included in the regular survey schedule of the committee. With this limitation, the sub-committee did not include much information of interest to those with special interest in the problems of industrial hygiene, because such information as, for example, provisions for the diagnosis and treatment of contagious diseases, venereal diseases, and tuberculosis, and provisions for various clinics, maternal, infant, dental, school, etc., is already provided for in the regular schedule.

SURVEY SCHEDULE FOR INDUSTRIAL HYGIENE

1. Tabulation of Industries

(Include only organizations employing 25 people or more in cities under 50,000 and 50 or more in cities over 50,000.)

LIST INDUSTRIES ACCORDING TO THIS CLASSIFICATION	NUMBER OF EMPLOYEES					
	White		Colored		Total	
	M.	F.	M.	F.		
a. Industrial.....						
b. Commercial						
c. Mercantile						
d. Public Service						
e. Municipal.....						

NOTE: Append list showing name and nature of industries.

2. Health Service Carried on by Industries

Name of Firms	No. of Full-Time Physi- cians	No. of Part- Time Physi- cians	No. of Full- Time Nurses	Physical* Examina- tion on en- trance required	Periodic* Physical Exam. required	Health* Educa- tional Activities carried on	First Aid Facilities

* Check each column if activity is maintained. -

3. Services for Municipal Employees

(Check the following service carried on by the municipality to conserve the health of its own employees.) .

Physical examinations
Vaccinations
Medical treatment
Hospitalization
Sick relief
Health instruction

(Append description of outstanding services)

4. Dispensary and Hospital Facilities in City

(This item to be obtained only when hospital survey is not being made)

Name of Institution	Dispensary		No. Hos- pital Beds	Beds per 1,000 Pop.	Per Cent Occu- pancy	No. Hospital Days			
	NUMBER					Free	Part Pay	Full Pay	Total
	Cases	Visits							

5. Occupational Hazards and Diseases

a. Specify any occupational diseases and number of cases reported from this community last year:

Diseases	No. Cases
.....
.....
.....
.....

6. Health Supervision of Industries

- a. Does the state health department take any cognizance of industrial hygiene? In what manner?
 - b. Does the municipal health department or other municipal agency take any cognizance of industrial hygiene? In what manner?
 - c. Does the municipal health department utilize industrial approach in carrying out preventive or educational measures?
- If so, how?

7. Legislation Affecting Health in Industries

- a. What occupational diseases are included in state compensation law? (List)
- (Attach copy of law)
- b. Attach copy of laws regulating employment of women and children

NOTE: The above schedule has been approved by the Committee on Administrative Practice of the American Public Health Association for use in collecting additional information to that called for in the *Appraisal Form for City Health Work* (3d ed.), 1929.

Delta Omega Publication

A 20-page pamphlet giving the list of members of Delta Omega, with their present addresses and their academic degrees, has been issued. This honorary public health society was organized in 1924 at the Johns Hopkins School of Hygiene and Public Health and now has 6 chapters and 250 members.

It is interesting to note that the most popular degree represented among the members of the society is the doctorate of public health (Dr.P.H.), which is held by 69 persons. Twenty of the medical graduates have obtained certificates in public health (C.P.H.) without other public health degrees, while 5 have taken the doctorate of science in hygiene (Sc.D.).

Among the 129 non-medical sanitarians, the doctorate in science has been the most popular, as there are 30 such degrees. Doctors of philosophy are also numerous, 26 being listed, though mostly among faculty members. Fifty-seven of the 250 members are listed as holding only bachelor or master degrees, or certificates in public health. Many of these are, however, candidates for various doctorates, though a considerable number are already actively engaged in public health work.

In tabulating the occupations of the members of the society it is significant that the largest proportion are teachers, though of course many are connected with the faculties of the institutions having chapters. About 30 are with other universities. State health departments claim 24, and local health work only 14, according to the available records. Another 25 are associated with voluntary health agencies. Only 31 of the total of 250 members are listed as being outside of the United States. These figures give an interesting indication of the type of training of present-day sanitarians and their field of activity.

Effect of Dust on the Lungs*

JUDGING from the number of investigations carried out during the past few years on the incidence and physiological effects of dust on persons employed in various industries, consideration of the hazard is assuming more and more importance in the minds of those concerned with public health.

The present report deals principally with the incidence of silicosis and does not take into account other health hazards that may be present in the dusty trades.

OCCURRENCE OF SILICOSIS

This disease, which is distributed in all parts of the world, is found in many industries, such as metal mining, the quarrying and dressing of granite, sandstone, millstone, and flint, the refractory industry, and in sandblasting.

In an investigation into the health and working conditions of employees in the mining industry of Australia carried out in 1928,¹ it was found that silicosis and tuberculosis, either singly or combined, exist as industrial diseases among the employees of the mining industry in Tasmania, as well as in Victoria. Gold mining in Victorian mines is a much more potent cause of industrial pulmonary disease than work in the Tasmanian copper, silver-lead, and tin mines.

Recently in a report on "The Present Position of Silicosis in Britain," *The Lancet*² quoted statements by Dr. Middleton, the medical inspector of factories, calling attention to the occurrence of the disease in various industries throughout the country.

According to Dr. Middleton the sandstone industry represents the most widespread of all silicosis producing industries, but the incidence of the disease is diminishing owing to the application of water and mechanical methods of dust suppression. The granite industry, although allied to sandstone quarrying and dressing, is complicated because of the varying proportions of quartz, feldspar, and mica present in the rock. As the result of an inquiry into the slate industry there appears to be some evidence of the production of fibrosis of the lungs, but the occurrence of actual disability within the ordinary working lifetime of workers is not clearly shown.

In the grinding of metals, silicosis, and especially the combined disease of silicosis with tuberculosis, was at one time extremely prevalent, but the sandstone wheel is being largely replaced by wheels of abrasives such as carborundum. Allied to the grinding of metals is the process of sand blasting metals and etching

* Report of the Committee on Silicosis presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

glass, by playing a jet of sand under high pressure against a metal or glass surface to produce certain effects. The process is becoming more extensively used, and it is a matter for serious consideration whether a substitute such as iron or steel grit could not be used to replace the siliceous grit as the abrading material. In pottery manufacture, both in the manufacture of earthenware and of china, Dr. Middleton suggested that "potter's asthma" is due to dust containing ground flint. Ground silica is used in many industries, and, in the crushing and grinding of the silica and in the industries in which ground silica is used, silicosis, sometimes of an acute type, occurs. The evolution of dust in these industries is controlled by the use of mechanical methods of handling, enclosure of machinery, and the use of localized exhaust draught.

Tin mining in Cornwall has had a high mortality rate from tuberculosis, and it has been shown that this is associated with silicosis. Drilling of the highly siliceous rock in which the tin ore occurs is now done through hollow steel with a water feed. Silicosis also occurs in coal miners employed on hard headings.

The report also states that the ganister and silica bricks manufactured in the refractories industry contain over 90 per cent of silica and that a medical board composed of specialists periodically examines each of the 2,000 or 3,000 persons employed in this industry.

According to Stewart³ in districts of Lancashire County, England, where the industry of coal mining predominates (40 per cent of the occupied males being engaged in mining), the male death rate from pulmonary tuberculosis is higher than the corresponding rate for the whole administrative county. Since the death rate from pulmonary tuberculosis among all coal miners of England and Wales is below that for the general population, the statistical evidence suggests strongly that there is in Lancashire an occupational factor at work that raises the death rate among miners, and that this factor is silicosis.

An inquiry was made by Sutherland and Bryson⁴ to obtain evidence regarding the occurrence of silicosis among workers in England manipulating sandstone in connection with the granting of compensation to sandstone workers since February 1, 1929, under the Workmen's Compensation Act of 1925. The findings disclosed that 1 out of every 4 men at work appeared to be the subject of "mason's disease." Since the men were all examined at work, any case so far advanced as third stage, and also many in the second stage, would not be found at work.

In an investigation of health conditions in a sandstone paving stone quarry, which had been in operation near Paris for 50 years, it was found⁵ by a study of mortality records that for the period 1881 to 1926 all the deaths occurring among the workers were attributed to respiratory diseases.

In Germany, according to Teleky,⁶ in spite of outstanding improvement in conditions, the mortality from tuberculosis is very high among metal polishers—higher than among similar mining groups. He considers sandstone to be the most dangerous grinding stone and recommends the substitution of artificial stone and the introduction of other protective measures such as dust removal, reduction of working time, separate rooms for polishing, and medical supervision.

At the suggestion of the county industrial physician, the Tuberculosis Hospital at Schwetzingen⁷ examined 23 of the men engaged in sandblasting in a metal polishing plant after it had been observed that several of the workers were affected by lung diseases. Of the sandblasters examined all except 2 complained of troubles. This report emphasizes the finding that the pneumoconiosis caused by sand dust

is more dangerous than anthracosis. The time of activity of these men in this industry was comparatively short; in most of the cases there was a pronounced roentgenological finding and in some changes of great severity and extent were observed.

An X-ray and clinical examination of 282 workers, who had been employed for 15 years or more in the most dust producing operations of a porcelain factory in the vicinity of Moscow, Russia,⁸ showed an unexpectedly low percentage of pneumoconiosis. This was the more surprising as porcelain dust contains large amounts of SiO_2 . Of the 282 workers examined, 24.1 per cent showed suspicious indications of pneumoconiosis and 13.5 were definitely affected by the disease.

At the meeting of the Permanent International Commission for the Study of Industrial Diseases, which was held in Lyon, France, April 3-6, 1929,⁹ Dr. Irvine in his paper, "Diagnosis of Silicosis as an Occupational Disease," gave the following figures regarding the incidence of silicosis among European miners on the Witwatersrand:

During the past 11 years, 4,092 cases of "simple silicosis," 377 "tuberculosis with silicosis," and 365 cases of "simple tuberculosis" have been detected by the Medical Bureau among the working miners on the Witwatersrand. Reduced to average figures these numbers represent in the case of "simple silicosis" alone an annual "production" of 372 cases among a population of 13,436 working miners; so that the average annual rate of incidence for the whole period was 2.76 per cent.

So far, reported studies of silicosis have been made for the most part on industrial groups in which the existence of silicosis as a hazard was deducible *a priori*. In the Industrial Department of the Vanderbilt Clinic, the occasional worker who appeared, giving a history of rock drilling in subway or tunnel construction work in New York City only, and who showed on X-ray examination of his lungs well-marked evidence of silicosis, aroused speculation as to the extent to which silicosis develops under conditions of excavation and tunnel construction in this city.

Of 208 men engaged in occupations exposing them to rockdust in Manhattan, who were selected for complete study, 57 per cent showed the presence of silicosis; 23 per cent showed radiographic evidence of ante-primary silicosis; 19 per cent of first stage silicosis; 7 per cent of second stage silicosis; and 8 per cent of third stage silicosis.¹⁰

In a study made of the abrasive industry, Clark¹¹ found that of a total of 137 workers exposed to large doses of dust, mostly from abrasives, over periods varying from 10 to 42 years, 42 showed no silicosis, 12 showed slight silicotic change, 77 the picture of first stage, and 6 the picture of second stage silicosis. Of the 6, 2 had been exposed to large doses of clay dust containing 9 per cent of free silica, 4 had been exposed to abrasive dust only. There were 11 cases in which the X-ray showed an old inactive tuberculosis process in the lung.

AGE INCIDENCE AND INFLUENCE OF LENGTH OF EMPLOYMENT IN THE DUSTY TRADES

Inquiry into the age incidence of industrial pulmonary disease among miners examined in Australia¹ shows that, while pulmonary tuberculosis may occur in early life, silicosis is a disease of slow evolution and does not appear frequently under the age of 40, and a period of at least 10 years in the industry is necessary to produce it. However, reports on other industries, such as sandblasting and the

pottery industry, would indicate that under some conditions the disease appears earlier. In the pottery industry in England¹² it has been found that in occupations where the occurrence of silicosis is high the disease becomes evident at an early stage in the occupational history of the worker. Sutherland and Bryson state⁴ that where the risk is present in the sandstone industry, the disease is much more common after 40 years of age and after 20 years of work in the industry.

According to Mavrogordato,¹³ on the Witwatersrand, among miners who develop silicosis, the mean duration of exposure before the disease is clinically recognized is from 10 to 11 years, whereas in the British pottery industry it appears to be about 25 years. He states, however, that although dust is easier to control in a pottery than in a mine, the potters start work much younger than do the Witwatersrand miners and continue in the occupation much longer. Nevertheless the actual annual silicosis rate of the potters appears to be about the same as that of the miners.

In the sandblasting industry, Müller⁷ found more severe pneumocotic lung changes with proportionately shorter activity not only among older workers but also among the younger ones, although X-ray examination revealed more severe changes in the older people than in the younger when the time of activity in the industry was the same. Thus, the average age of the workers, examined by Müller, who had more severe lung changes, was 45 years, while the average age of the other workers was 32.6. The time of activity in the industry was with all comparatively short—with one worker 8 years, with one 6 years, and with all the rest under 3 years.

In the porcelain industry, according to Kaestle,²⁴ workers hardly ever show characteristic pneumoconiosis under 10 years of work; but in the case of older workers with relatively short working time he found the changes to be clearer and more stubborn than in younger employees of similar working time. He considers that the vitality of the whole man and of the respiratory system plays an essential rôle in the prevention of damage and the self-purification of the intruded dust. He also recommends that only those who have reached a certain bodily maturity be employed in this occupation, since the self-purifying ability of the lungs is greater if the worker is not very young or very old.

In the investigation in New York City¹⁰ it was found that 76 men, or 36.5 per cent, had been exposed less than 10 years, while 132, or 63.5 per cent, had been exposed 10 years or more. The shortest exposure in the entire group was 6 weeks; in the ante-primary group it was 3 years; in the first stage group it was 1 year, and in the second and third stage groups it was 9 years. The longest exposure in the entire group was 46 years. In the ante-primary group it was 40 years; in the first stage group, 46 years, and in the second and third stage groups, 44 years.

According to Hamilton,¹⁵ in the enamel-ware industry, in spite of the improvements that have taken place, it is a significant fact that the working life of an enameler is still short, although his wages are good and his hours often less than the average. One large plant points with pride to a veteran who has worked at the trade for 22 years; another has one with 18 years of service. Since the men start in at 18 or 20 years of age, it is plain that the great majority must give it up before they reach the age of 40 years.

From June, 1927, to December 31, 1928, there were made 15,351 physical examinations of men and 400 of women and children at the U. S. Bureau of Mines Health Clinic, Picher, Okla. This year's work so far indicates that there has been

a reduction in the number of silicotics working in the mines in this district. Much of this reduction is due to the silicotics leaving the mines. A great many of these men have either been given suitable treatment in hospitals, sanatoriums, etc., or have been provided with suitable work outside of the mines.

An investigation, begun in 1926, and reported recently,¹⁶ was made by Hayhurst and his coworkers, in one of the largest and deepest sandstone districts in the world, located in Ohio and worked for more than 50 years. The workmen are employed by two quarry companies which market grindstones, scythestones, curbing, flagging, breakwater and building stone, and also furnace sand. The report summarizes the results as follows:

A stereoscopic X-ray examination was made of each of the 919 workmen, of which number the films of 913 workmen were readable. Of this latter number, pulmonary pathology was found in 55.1 per cent, including 38.5 with silicosis in various stages. The total tuberculosis, however, was but 1.9 per cent. Likewise general disability was low. These findings check relatively closely with those of the tuberculosis statistics for the community. The period for developing silicosis, namely, 16.24 years, is over twice that reported elsewhere. The rock has an average content of from 92.15 to 97 per cent crystalline silica (SiO_2).

A study of silicosis reports throughout the world indicates that tuberculosis is usually present in from 20 to 30 per cent or more of the cases of silicosis, but of our 260 men with silicosis only 13, or 5 per cent, had tuberculosis.

The authors suggest that other silicosis studies at this quarry should include a careful analysis of the rock itself, from both chemical and petrographic points of view.

A few years ago, the U. S. Public Health Service¹⁷ began a series of intensive studies on the health of workers in dusty trades. The first study was reported in 1928, and dealt with the health of workers in a cement plant. The report on the second study,¹⁸ dealing with the health of workers exposed to silica dust in the granite-cutting industry, has recently been published.

This report brings out clearly the extent of the hazard under such conditions as existed in the plants studied. Of particular importance is the fact that it was possible, by differentiating occupations on the basis of the amount of dust exposure, to determine within broad limits how much dust of the composition studied can be tolerated by workers without serious deleterious effects. The conclusion was reached that a maximum of dust exposure falling somewhere between 10 and 20 million particles per cu. ft. of air is a desirable limit for dust containing about 35 per cent free silica in the form of quartz. It was also concluded, on the basis of a study made in other plants having local exhaust ventilation systems, that this limit could be reached by the use of economically practicable ventilating devices of this character. The recommendation was made that occupational processes in which little dust is produced be segregated in separate rooms or buildings.

It should be pointed out that the limit established was not found to prevent the occurrence of silicosis. It was found, however, that there seemed to be no particular liability to pulmonary tuberculosis where the concentration of dust was within this limit.

The study was of such a character as to present a rather definite picture of what happens to men working for many years under a dust hazard of the extent described. The salient points may be summarized as follows:

1. The long period of service before the liability to tuberculosis becomes manifest (generally 20 years or more)
2. The sharp correlation between length of exposure to the dust and the prevalence of tuberculosis and also the death rate from this disease
3. The close relation between the extent of dust exposure and the health of the men
4. The universal occurrence of silicosis among the workers
5. The large proportion of workers finally succumbing to tuberculosis
6. The almost invariably fatal form of the disease within a short time after the onset
7. The different character of silicosis as manifested by X-rays compared with that shown where there is exposure to a dust with a much higher content of free silica
8. The location of the tuberculosis lesion, usually basal, where the disease complicates silicosis
9. The absence of deaths from silicosis *per se*, tuberculosis apparently always intervening
10. The failure of workers to recover from their condition upon going into non-dusty trades
11. The high incidence of sickness of a severe nature from causes other than tuberculosis
12. The rising sickness and mortality rates from tuberculosis due to longer use of the hand-pneumatic tool
13. The high death rates at the present time from tuberculosis, compared with normal industrial experience

ETIOLOGY OF SILICOSIS

Miners who have silicosis, according to Tattersall,² will be found without exception to have been engaged principally in drilling or hewing stone. The abnormal appearances in the lungs of the gold miner, the stone mason, the quarryman, and the coal miner are similar although the constituents of the dust may vary, indicating that the silica and that alone gives rise to the pathological condition.

According to a paper by Heffernan³ on the biophysics of silica and the etiology of silicosis, the disease is the result of the local action of hydrated silica upon the pulmonary tissue; this action is physico-chemical in nature and its development depends upon the rapidity with which fresh silica hydrosol is brought into contact with pulmonary tissues; substances, such as alkalis, which favor the formation of silica hydrosol from silica, when added to silica dust accelerate the development of the silicosis; and substances, such as carbon, coal dust or clays, which retard or prevent the formation of hydrosol from silica or which coagulate the hydrosol when formed, retard or prevent silicosis.

In Australia some evidence was noted that silicosis complicated by tuberculosis may occur earlier than uncomplicated silicosis.

Stewart⁴ calls attention to the fact that the precise manner in which the silica acts upon the lung tissue and renders that soil favorable for the development of tuberculosis is still a matter of controversy, one view being that the silica acts as a soluble protoplasmic poison, the other view being that colloidal silica is formed which acts in an adsorbent way on the protoplasm of the cells containing the silica, forming a pabulum which is a favorable soil for the growth of tubercle bacilli.

Stewart considers that there is no doubt that when silicosis and tuberculosis are both present, tubercle bacilli are often extremely difficult to obtain; that such a case may proceed to a fatal termination without tubercle bacilli being found, and yet extensive tuberculosis be found post-mortem in addition to the silicosis. According to him, the question of the infectivity of these combined cases of tuberculosis and silicosis is an interesting one. There is a good deal of evidence available pointing to low infectivity as compared with cases of simple pulmonary tuberculosis. The evidence in his own dispensary area (southeast Lancashire) tends to confirm this view, as the number of positive contacts from such cases has been few compared with contacts from patients with simple pulmonary tuberculosis.

Stewart also called attention to the point of controversy as to the priority of the two conditions, whether the silicosis is antecedent to the tuberculosis or *vice versa*. Dr. Watkins-Pitchford in South Africa thinks that the great majority of cases of simple silicosis would not have developed into such but for the presence of a tuberculous element in the lungs. According to Stewart, clinical evidence neither proves nor disproves this view.

In France a histochemical study was made of lungs taken from subjects having lived in the city and never having worked in coal mines²⁹ and in another study by the same investigators³⁰ a cytological and histochemical examination was made of the lungs showing 4 typical cases of anthracosis in miners in Courriere. According to these investigators these studies have enabled them to contribute some new results in regard to the much discussed problem of the nature of anthracosis pigment, whether the ferruginous pigment found is derived from blood or from masses of exogenous particles of coal introduced by respiration.

From these studies the following conclusions were drawn: A small part of the pigment encountered in the anthracosis of miners is certainly formed by a substance derived from hemoglobin, yielding red ashes of iron oxide. The other part, by far the more important, is formed by a pigment which disappears by incineration without leaving any residue of iron oxide. This pigment, which is extremely abundant, can be considered either as a non-ferruginous endogenous pigment or as from coal. The authors think that the latter interpretation is correct for the two following reasons: The particles of this pigment are extremely irregular and non-spherical, as those of an endogenous pigment. They coexist always with other particles of a mineral nature, which on incineration leave an abundant residue of calcarious and silicious ashes. This constant existence of silicious minerals and black pigment indicates that this latter is coal. The coal dust is fixed in the lungs exactly as the silicious dust.

According to Mavrogordato, pigmentation facilitates the tracking of dust by the naked eye, but is not an essential part of the changes produced by dust of free silica. If silica particles be injected intravenously, some pigmentation is to be observed on intracellular particles and this pigment is probably a hemoglobin derivative. He considers the point to be rather of interest than importance, as far as silica itself is concerned, and calls attention to the fact that Virchow, until Zenker convinced him to the contrary, regarded pigmentation in dust-phthisis as due to a breakdown of hemoglobin, and not to the dust inhaled. When one turns to the metallic dusts—cobalt, iron or vermilion, for instance—one is reminded of the work of Mallory and others on hemochromatosis and feels that, in these cases, the part played by the breakdown of hemoglobin may be more significant. The presence of carbon in the air does not appear to effect the changes produced by silica other than by coloring them, and the tissue changes, detailed above, according to

Mavrogordato, can be produced by silica alone, and a silicotic lung need show very little pigmentation.

Mavrogordato summarizes³³ the current views on the etiology of silicosis under two headings: 1. Cases of uncomplicated silicosis, in which no infective element is present; and 2. Cases of silicosis complicated by infective processes, of which the most common is tuberculosis. He asserts that certain industries are "phthisis producing" and defines such a dust under four headings as follows: (a) Its nature, (b) size of particles, (c) faculty of being arrested in the tissues, and (d) concentration of dust, duration of exposure and conditions of exposure.

According to him, a phthisis producing dust arrested in the lungs in sufficient quantity will set up a fibrosis, but will not produce a true "miners' phthisis." The effective occupation of the lungs by a phthisis producing dust facilitates infection by the tubercle bacillus, and may influence the result of infection by certain other organisms. Clinical silicosis and fibrosis in the presence of a phthisis producing dust implies arrest of dust in the lungs. The lungs may, however, be effectively occupied by dust clinically undemonstrable yet capable of influencing an after-coming infection. The disabling and fatal form of miners' phthisis, as now met with on the Witwatersrand, he considers is due to an infection by the tubercle bacillus superimposed upon lungs effectively occupied by a phthisis-producing dust. This event may or may not be preceded by a definite clinical silicosis. Delayed resolution and chronic progressive changes may occur in lungs effectively occupied by a phthisis producing dust after recovery from acute pneumococcal or streptococcal infections.

PHYSIOLOGICAL ASPECTS

There is not much new material along the lines of symptoms, diagnosis, treatment and prevention, efforts of investigators apparently having been devoted mostly to the determination of the presence of the disease in various industries.

Irvine⁹ stressed the importance of the infective factor in silicosis and emphasized the fact that it is uncommon to find a condition of clinically obvious tuberculosis present at the stage at which silicosis first becomes detectable. The very great majority of cases of silicosis found among working miners, when first detected, are from the clinical standpoint cases of uncomplicated or "simple" silicosis, without evidence of obvious or "overt" tuberculosis. Nevertheless, "simple" silicosis should not be thought of merely as a dust fibrosis, but as being at least in a majority of cases a dust fibrosis which from its beginning as a clinically detectable condition is linked up with an element of latent tuberculous infection. The after-history of these cases is in this respect significant. In the majority of instances silicosis is a progressive disease. The outlook of the individual case is mainly dependent upon whether the infective element remains "bottled up" and inactive, or whether, on the other hand, it becomes active, or a further infection occurs from outside the lung. In some instances advance is rapid; in others, again, the condition may remain stationary practically indefinitely. But, although there are wide individual differences, dependent no doubt in part upon constitutional, nutritional and environmental factors, yet the tendency of the majority of cases to advance is, on the average, singularly uniform, and the culmination of that advance, if it proceed to its terminal stage, is in a form of obvious active tuberculosis in the silicotic lung, although by no means all cases advance to that condition.

There is some disagreement in regard to the suggested treatment by the administration of some non-silicious dust, such as coal dust, that is apparently harmless and will assist in removing the harmful dust from the lungs.

Dr. Middleton states that it would appear that once enough silica has been inhaled to produce the nucleus of fibrosis, the resulting inhalation of coal dust into a lung in which the lymphatic drainage has been disorganized increases the fibrosis and produces disability.

Kaestle considers that even with the conviction that dust and bacilli can be forced into the respiratory organs in various similar ways, the attempt of such inhalation therapy is driving out the devil with Beelzebub, a very problematical healing of tuberculosis purchased by the certainty of dust lungs.

Mavrogordato states that, according to experimental studies, a phthisis producing dust and an infective agent simultaneously present facilitate each other's action in the direction of producing fibrous tissue. No experimental evidence could be secured suggesting that the presence of coal dust in the lungs exercised a protective action against tuberculosis. The simultaneous inhalation of coal dust and silica dust facilitates the exit of silica laden cells from the lungs, but a lung previously invaded by coal dust has no special ability to rid itself of silica. As already mentioned, a lung invaded by silica retains the fine soot from acetylene lamps.

Müller⁷ points out the injustice of not recognizing as occupational the diseases of sandblasters, resulting from their employment, as lead poisoning is in the case of lead workers. However, in England this is done under a scheme of the Workmen's Compensation Act of 1925. In February, 1929, a new scheme became effective known as the Sandstone Industry (Silicosis) Scheme.⁴ Some of the provisions of the scheme are that a register, supplied by the employer, must be kept by the worker and produced when required by the employer or the Medical Board, on which shall be entered date of commencement of his employment with employer, particulars of any previous employment in the sandstone industry or in any of the occupations mentioned in the First Schedule to this Scheme, and date of medical examination entered by the Medical Officer making the examination. The workman will be liable to forfeit his right to compensation if he fails to furnish true information or carry out other specified duties under this scheme. In case of a workman employed in the industry on or after April 1, 1929, or in case of death, his dependants will be entitled to compensation, if his death or disability is caused by silicosis. The disease must be due to employment in the industry, and will be so considered if the workman has been employed for a period or periods amounting to not less than 5 years, unless the employer or the company proves the contrary.

If the employer fails to carry out any of his duties he will be liable to pay an increased subscription to the Compensation Fund. The Scheme requires the employers to furnish facilities for the periodic medical examination made at the works and not, without the consent in writing of the Medical Board, to engage or to continue to employ in the sandstone industry any workman who has been suspended under the Scheme or who has refused to submit himself to any examination required under the Scheme. If the workman refuses or wilfully neglects to submit himself to any such examination or in any way obstructs the same, or if after having been suspended he without consent in writing of the Medical Board reengages in the sandstone industry, he will be liable to forfeit his right to compensation.

All investigators agree that efficient methods of removing or allaying dust, ex-

amination of men before beginning work in the dusty trades and periodically thereafter with the elimination of the tuberculous, are of value in the prevention of silicosis. Although the rule holds that once silica invaded always silica occupied, the lungs have considerable powers of ridding themselves of silica laden cells. This is borne out by observations made on South African native miners³³ who, for the most part, work short contracts interspersed with visits to the kraals and it is surprising how comparatively little naked-eye pigmentation there may be in the lungs of a man who had worked several underground contracts and has afforded opportunities for observation owing to his death from an accident immediately on resuming work after an interval.

According to Mavrogordato, this indicates that intermittent, as opposed to continuous, employment is perhaps the most effective single measure against silicosis. He states that the simple silicosis rate among native miners employed on the Witwatersrand is lower than that among white miners, although the native, when at work, is more exposed to dust than is the white miner. His employment, however, is intermittent as compared with the continuous employment of the white man. A study of a small group of natives who had been employed continuously showed about the same simple-silicosis rate as obtained among white miners; in fact, the mean duration of exposure before disease was recognized in the continuously employed native was less than that in the case of the white man.

SUMMARY

Consideration of the dust hazard in industry, if judged by the reports appearing during the last year, is assuming more and more importance from the standpoint of public health.

The sandstone industry, according to reports, represents the most widespread of all silicosis producing industries. Investigation of this industry in England in connection with the Workmen's Compensation Act showed that 1 of every 4 men at work appeared to be the subject of "mason's disease." Silicosis is found among the metal polishers, metal miners, sandblasters, potters, and any other workers exposed to dust containing free silica. There is a difference of opinion as to free silica being the only causative factor as in New South Wales silicosis has also been found to be caused by orthoclase basalt, which does not contain free silica.

Silicosis may be classed under two headings: uncomplicated silicosis, in which no infective element is present; and silicosis complicated by infective processes, of which the most common is tuberculosis.

Histochemical and cytological studies made on the lungs of miners showing anthracosis and on those of non-miners indicate that the ferruginous pigment found in the lungs of both miners and non-miners is derived from the blood and not from exogenous substances inhaled by them.

Studies made by the U. S. Public Health Service in the granite industry show the close relation between the extent of dust exposure

and the health of the workers. The occurrence of silicosis is universal among them and a large proportion finally succumbs to tuberculosis, death apparently not taking place from silicosis *per se* without the intervention of tuberculosis. The death rate from tuberculosis is high in this industry when compared with normal industrial experience.

South African investigators think that "simple silicosis" should be considered in a majority of cases as a dust fibrosis linked up, from its beginning as a clinically detectable condition, with an element of latent tuberculosis.

A number of authorities stress the progressive character of silicosis since, although there are wide individual differences dependent no doubt in part upon constitutional, nutritional, and environmental factors, the tendency of the majority of cases to advance is singularly uniform and the culmination, if it proceeds to its terminal stage, is in the form of obvious active tuberculosis in the silicotic lung.

There is a difference of opinion in regard to the suggested treatment by the administration of a non-silicious dust, such as coal dust. Middleton thinks that once enough silica has been inhaled to produce the nucleus of fibrosis, the resulting inhalation of coal dust into a lung in which the lymphatic drainage has been disorganized increases the fibrosis and produces disability. Mavrogordato has been unable to secure experimental evidence indicating that the presence of coal dust in the lungs exercises a protective action against tuberculosis but thinks that the simultaneous inhalation of coal dust and silica facilitates the exit of silica laden cells from the lungs, although a lung previously invaded by coal dust has no especial ability to rid itself of silica.

All investigators agree that efficient methods of removing or allaying dust, examination of men before beginning work in the dusty trades and periodically thereafter with the elimination of the tuberculous, are of value in the prevention of silicosis. Although the rule holds that once silica invaded always silica occupied, the lungs have considerable powers of ridding themselves of silica laden cells. According to Mavrogordato this is borne out by observations made on South African native miners who, for the most part, work short contracts interspersed with visits to the kraals and he was surprised how comparatively little naked-eye pigmentation might be in the lungs of a man who had worked several underground contracts and had afforded opportunities for observation owing to his death from an accident immediately on resuming work after an interval.

Camp on Lake Worth, Texas

Organization of Local Health Area Statistics in New York City*

GODIAS J. DROLET AND WILLIAM H. GUILFOY, M. D.

*Statistician, Research Service, New York Tuberculosis and Health Association ;
and Registrar, Bureau of Records, New York City Department of Health,
New York, N. Y.*

IN a great city like New York, with a population of 6 million swollen to more than 8 during the day by workers and visitors, and spread over an area of 309 square miles, in what direction and among whom is public health work going to be directed economically and effectively? Where are new hospitals needed, new health centers or clinics to be established?

For the systematic and continuous consideration of local health needs, the Department of Health, the Welfare Council, the Milbank Memorial Fund, and the New York Tuberculosis and Health Association have coöperated in developing a plan for the organization of local health area statistics in 270 districts throughout New York City.

Not only New York but all large cities are badly in need of neighborhood health data; general death rates are too often only theoretical mid-points not representative of many sections. Special studies in Bellevue-Yorkville¹ disclosed that in certain sections the death rate, standardized for age and sex, and based upon data for a 5-year period, varied from 12.3 per 1,000 to 24.2 when the district rate averaged 17.0, and that of the entire city was only 12.5. Without definite knowledge as to where "the dark areas" are, public or private health work is too frequently a wasteful barrage instead of a direct, economic and successful attack. Clearly defined health area units must be recognized in large cities; and standard, comparable vital statistics should be continuously available for each. The steps taken to secure this for New York City are the subject of this address.

HISTORICAL

For years, there had been available certain population data and very limited mortality statistics by wards or by political boundaries.

* Abstract from paper read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

As time went on these units became most unequal in population; thus, in 1920 the Second Ward in Manhattan showed a census of only 372 and the Twelfth Ward of 951,904. Federal or state censuses naturally publish their returns along frequently changed political boundaries. It therefore became practically impossible to maintain useful local vital statistics along these lines.

In 1906 the U. S. Bureau of the Census greatly assisted in making possible a remedy for the situation. The federal authorities adopted the plan of the New York Federation of Churches "for a scientific permanent basis for neighborhood tabulation of the population of New York City." Enumeration districts¹—approximately 40 acres each in the populous sections, and multiples thereof in neighborhoods sparsely settled—were laid out and have been followed for each of the last two federal censuses. Since 1910, thanks to the special tabulations by the Population Research Bureau of the Federation of Churches, and its successor the Cities Census Committee,² all the usual population data have been made available for these units. In 1914 the Department of Health recognized the census tracts as "sanitary areas" to be followed in constructing new administrative districts in tuberculosis clinic work, baby health station districts, etc.

But even with this progress, certain difficulties and needs remained as regards neighborhood health data: (a) The population in the uniform 40-acre tracts had been found to vary widely, and at times to be quite insufficient for a statistical basis. (b) To code and tabulate data for only Manhattan was found an arduous task when each of the 224 sanitary areas of the 1910 map were recognized. (c) In Greater New York, the 1920 census map recognized no less than 3,427 areas. To attempt the segregation and tabulation of the vital statistics for each of these tracts—not to mention the cost of publishing the tables occasionally, if not currently—was practically impossible. (d) There was also a realization that the ordinary mortality statistics before being utilized and compared should be qualified by sex and age. (e) Finally, there has been the migration from Manhattan to the other boroughs.

The need of adequate vital statistics by neighborhoods in New York, yet gathered along practical lines that could be kept up and currently published, led to the creation in 1927 by the Welfare Council of a committee to consider the problems involved in "Local Statistics required for District Health Work."* The report adopted³ covered several essentials; it indicated that "Four basic types of information

* The Committee appointed by Dr. Haven Emerson consisted of *Chairman*, Godias J. Drolet, Shirley W. Wynne, M.D., Thomas J. Riley, Ph.D., and Jane M. Hoey.

should be available: population, health data, volume of local health work, and cost of local health work."

The most practical service rendered by the committee was in securing an agreement on what should constitute a "Health Area Unit." The report stated that "The geographic unit for statistics of local health work in New York should consist of a group of sanitary areas† aggregating approximately 25,000 population"; and "A reconsideration of the geographic units should take place every 10 years after the local results of the federal census are available." Thereby two achievements were realized: first, an opportunity to meet inequalities of growth and to continue the preparation of local facts on a somewhat comparable basis; and second, the recognition by official and private health authorities of a workable number of health areas, 270 for Greater New York.

Of these health areas, built up by combining the smaller and too numerous sanitary areas, Brooklyn, with its population of 2,300,000, has 92; the Borough of the Bronx, with 950,000 population, 48; Queens, with 850,000 people, 39; Staten Island, with 150,000, 10. For the older Borough of Manhattan, with 1,750,000 population, where for years there had been a careful tabulation of all the essential vital statistics for each of 224 sanitary areas, it was decided to maintain the continuity of the data, but to publish them in comparable aggregates as in the other boroughs for 81 health areas only. In each borough, one health area was set aside for parks and cemeteries.

The Welfare Council report recognizing that knowledge of the local population was also required for district work recommended not only an irreducible minimum of items in each unit, consisting of sex, color, nativity, and of seven age groups, but also pointed out that data on occupation and civil status should also be had, and that "health and social agencies . . . should indicate to the state and federal authorities the importance of a census every 5 years in a center changing so fast as New York." Another significant recommendation was that "Enumerations should be taken not only of the night or home population of the various units in the city, but also, at least in Manhattan, of the day-working population—frequently more permanent in its place of employment than in its home."

As practically all of the recommendations of the report concerning local health data have been carried out by the New York City Department of Health, the mortality items covered and the methods followed will be taken up with the description of the actual work now under way.

† One of the smaller 40-acre census tracts, previously referred to and totalling 3,427 for all of New York City.

For each health unit comparable information on births, the more common infectious diseases, and leading causes of mortality was requested, with the recommendation that it be currently published for each area corrected on the basis of residence and not of occurrence, even for accidents.

ORGANIZATION OF HEALTH DATA

In 1928, both Health Commissioner Louis I. Harris, M.D., and his successor Shirley W. Wynne, M.D., approved the plan recommended. Pending municipal support, the Milbank Memorial Fund and the Welfare Council contributed together \$5,000 for clerical assistance to "initiate the compilation of local health statistics."

The next practical step taken was that of the Bureau of Records which prepared an original street index to permit proper assignment of the certificates and reports to be classified.

Certain important definitions in classifying by area of residence have had to be kept in mind. Fortunately for almost twenty years deaths in institutions have, in every case possible, been charged back to the borough of residence of the deceased. In a great city like New York there are also deaths of "unknown" persons or homeless and lodging house men, and of "non-residents" numbering more than 2,000 annually. The numbers of these in each area have naturally had to be stated separately from those for residents only.

The lesser section of local health area statistics in New York is that devoted to communicable diseases. Only ten of the more common conditions registered were recommended for inclusion: tuberculosis, diphtheria, measles, scarlet fever, whooping cough, typhoid fever, influenza, pneumonia, syphilis and gonorrhea, separately for males and females. Let us recall that the usual and complete lists of the reportable diseases and the full standard mortality data are being kept up for the entire city, and for each borough as well.

The task of performing properly the local segregation can be realized when it is seen that this will involve annually the additional coding and handling of at least 125,000 birth certificates and 75,000 deaths, beside the distribution of another 75,000 to 80,000 reports of infectious diseases.

The actual work of classifying local health data throughout the city was started at the beginning of 1929 and several abridged preliminary reports have already been published. The practical aspects of this new service to the community can be better understood by studying the items contained in a work sheet for a single district: First, in each area are the births according to residence of mothers,

separately for white and colored. Second, the mortality data are classified both by sex and color within each of seven age groups: under 1 year, 1 to 4 years inclusive, 5 to 14, 15 to 24, 25 to 44, 45 to 64, 65 and over.

With the comparatively small population included in the areas selected, around 25,000, it was considered essential to have not only the total number of deaths from certain causes, but also qualification of these by sex, color, and at least the more important age groups so as to permit even the standardization of the death rates and to allow thereby for the greater variation in age or sex composition likely to be found in smaller "communities."

In the complete original health area tabulations made in the Bureau of Records, the deaths are also classified separately within each of the following causes or groups of diseases: typhoid, measles, scarlet fever, whooping cough, diphtheria, influenza, poliomyelitis, encephalitis, epidemic cerebrospinal meningitis, pulmonary tuberculosis, other tuberculous diseases, cancer, diabetes, cerebral hemorrhage, heart diseases, arterial diseases, broncho-pneumonia, lobar pneumonia, diarrhea under 2, and over, appendicitis, chronic nephritis, puerperal septicemia, other puerperal causes, congenital debility and diseases of early infancy, suicide, accidents by automobiles, and by other causes, first, by place of occurrence and, second, by place of residence, homicide, other causes, total deaths charged to area, deaths of non-residents and deaths of area residents only.

Accidents, after being charged to place of occurrence, are redistributed to area of residence. This enables one to know also the full mortality, natural and accidental, of all residents of an area. The ordinary method of charging accidents to place of occurrence only, Drolet believes, may, in default of knowledge of the added working or visiting population during the day in business areas, mislead and vitiate the accuracy of the general death rate wanted for residents only.

PUBLICATION

The full tabulation of the reports of the principal communicable diseases and of leading causes of mortality, classified according to sex, color, and important age groups in each of 270 health areas in New York City, has already been completed for most of 1929, and practical use of it has been made by several health agencies.

The problem, however, of printing such detailed information currently and within reasonable cost has been only partially solved thus far. The original recommendation was for a quarterly bulletin, but Department of Health officials, concerned with sanitary supervision,

have pointed out that in the case of communicable diseases it would be more useful to have the bulletins issued at least monthly. The original 270 area records of mortality for the whole city with seven age classifications and a total for each area require 2,160 horizontal lines alone. And the 35 causes of death or groups of data, subdivided into sex and color, amount to 140 vertical columns.

Accordingly, while the complete tabulations, as described, are being kept up in the Bureau of Records, and access is readily granted to recognized agencies and institutions, it is now planned to publish complete tables only annually. However, in the meanwhile, an abridged issue is being published monthly. Economy has been secured by including only the totals, without age classification, but by color for births, deaths under 1 year, and 16 causes of mortality.

USE OF THE HEALTH AREA STATISTICS

Current use of the local reports of births, deaths, and of registration of infectious diseases is already being made by the Bellevue-Yorkville Health Demonstration. By aggregating the returns of the eight health areas in their district, the director of that interesting public health experiment is enabled to send each month to members of the local community health services and participating agencies not only a report on current administrative activities but also the latest information on prevailing contagion, as well as the returns of births and various causes of mortality. The opportunity to test the progress of local public health measures is immediate and there is a guide upon which to base programs in relation to actual needs.

At the East Harlem Health Center, and in the Bowling Green Neighborhood, similar mortality information for the smaller sanitary areas only, already available in the past for Manhattan alone, has been used for special studies of local health conditions.

The latest use of the local health area statistics is that recently inaugurated through Health Commissioner Wynne for a preliminary survey of health center work in New York. With the recent and great shifts of population in the various boroughs the question of locating properly, and where most needed, additional baby health stations, various clinics and new health centers is a constant one—in fact, after the establishment of important central services by the Department of Health the decentralization of certain public health activities is now urgent.

How to undertake neighborhood health work best; how to get near to and reach all sections of the people in a great community—for instance of 1,250,000 school children—is not easily answered. To per-

mit an intelligent consideration of basic facts and needs the Committee on Neighborhood Health Development is first utilizing the health area map, and in each of these units are being spotted existing hospitals, clinics, and schools; after this, are added the latest population figures for each health area, the school registration, and for the first half of 1929, the births, deaths, and cases of infectious diseases. With these data of possible local requirements for maternal and infant welfare work, school medical service, amount of required home sanitary supervision, local mortality rates, and finally of existing institutional facilities or knowledge of their absence, it will be a much more direct process to visualize health needs in every part of the city.

In conclusion, the authors remark that the majority of the American people now live in cities, many of them large; that the ordinary average vital statistics report for an entire community is insufficient to portray the diversified life in the urban centers; that the dependence for segregation upon ordinary political subdivisions is inadequate; that the use of reports of mortality within small units demands care in meeting differences of sex, age, or color; and, therefore, that we point out the practical experiment inaugurated for the current compilation and publication of local health area statistics along standard lines in each of 270 districts throughout New York City.

Vitamin Content of Ethylene-treated and Untreated Tomatoes*

D. BREESE JONES, PH. D., and E. M. NELSON, PH. D.

*Protein and Nutrition Division, Bureau of Chemistry and Soils,
U. S. Department of Agriculture, Washington, D. C.*

THE use of ethylene gas for the forced coloration of certain fruits and vegetables, such as citrus fruits, bananas, and tomatoes, has recently attracted much attention from both the commercial and the nutritional standpoints. By this process the development of color characteristic of the ripe fruit can be materially hastened in green, unripe fruit either before or after shipment; and the period during which the fruit can be stored, or shipped from warm to colder regions in advance of the local season, lengthened. It also results in products more uniformly colored, having a firmer texture, and less subject to injury from handling, than those allowed to ripen naturally before being gathered. Ethylene has also been found efficacious in removing the astringency of certain fruits, such as persimmons, due to the presence of tannins.

It has been long known that the coloring or ripening of certain fruits can be hastened by placing the fruit in closed rooms or tents in which oil or almost any other fuel is being burned. The effects were at first attributed to increased temperature and humidity. In 1912 Sievers and True,¹ working on the "sweating" process of ripening citrus fruit, discovered that the hastening of the coloring of lemons was caused by the action of gaseous products of incomplete combustion. Following up this work Denny² showed that the constituents of these gases that were most effective were unsaturated hydrocarbons, notably ethylene. In 1923 Denny³ secured a patent covering the use of ethylene for the forced coloration of fruit. Chace and Denny in 1924⁴ contributed additional data on this process.

The blanching effect of ethylene and other constituents of illuminating gas on plants had been early observed by Kroker and Knight,⁵ Schonnard,⁶ and others. Other contributions on the application of ethylene to the coloration of fruits and the blanching of celery have been made by Chace and Church,⁷ Rosa,⁸ and Harvey.⁹

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

Soon after the announcement of the ethylene process for treating fruits and vegetables, the *Journal of the American Medical Association*, recognizing the possible harmful effect upon their nutritive value that might result from chemical treatment of foods, particularly with reference to the vitamins, called attention¹⁰ to the need of work to develop information regarding the effect, if any, of the ethylene process on vitamins.

In view of the work that had been done in the U. S. Department of Agriculture on the study and development of the ethylene treatment of fruit, and in conjunction with a continuation of investigation on this subject by the Food Research Division of the Bureau of Chemistry and Soils, we undertook a study of the comparative vitamin value of tomatoes treated and untreated with ethylene gas, and collected at different stages of development.

PREPARATION OF THE MATERIAL*

The tomatoes used were a pure bred strain grown specially for the ethylene studies on the U. S. Department of Agriculture experiment farm at Arlington, Va.

They were collected at three stages of development, immediately washed with water, and handled as follows: Green tomatoes in two stages of maturity were divided into four lots. The lots to be treated with ethylene were placed in earthen jars; ethylene gas was introduced in the proportion of 1 part in 1,000; and the lids were sealed.

The tomatoes were removed from the jars daily, dried and aired, then replaced; fresh ethylene gas was introduced, and the jars were resealed. After treatment with the gas for 5 days, they were ground in a meat grinder, thoroughly mixed, heated in a steam bath, and placed in cans while hot, sealed and processed according to usual cannery practice.

The portions untreated with gas were ground as soon as picked, processed and canned in the manner and under conditions identical with those described for the gas treated tomatoes.

In addition to the green tomatoes referred to, others that had been allowed to ripen naturally on the vines were likewise canned.

There were thus prepared for the vitamin studies five different lots of tomatoes referred to as follows:

Lot 1—Mature, green tomatoes, untreated; i.e., full grown fruit in which the chlorophyl had begun to fade, but which were not ripe

* We are indebted for the material used in the vitamin studies described in this paper to Dr. F. C. Blank of the Food Research Division of this Bureau, under whose general direction the tomatoes were grown, collected, treated, and canned; also to Dr. L. H. James of the Food Research Division, who personally supervised the work in the preparation of the material.

Lot 2—Tomatoes naturally ripened on the vines—untreated

Lot 3—Immature, green tomatoes, walnut size, untreated, in which the chlorophyl had not begun to fade

Lot 4—Mature, green tomatoes, similar to *Lot 1*, treated with ethylene

Lot 5—Immature, green tomatoes, similar to *Lot 3*, treated with ethylene

After being canned, the tomatoes were placed in cold storage.

There were marked differences in the proportion of solid material to juice in the different lots. The cans of mature, ripened tomatoes contained more juice than did the green, immature fruit.

Since tomato juice is used extensively and frequently recommended in infant feeding, and our feeding technic could be greatly facilitated by using the juice, only that portion of the fruit which passed through a fine muslin cloth was used in our vitamin tests.

Owing to the possibility of retention of some of the vitamins in the pulp the results obtained may not represent the full vitamin potency of the tomatoes used. We were interested in comparative rather than absolute values.

The following observations on the canned fruit were noted: *Lot 1* showed the development of a little red color. *Lot 2* was more deeply colored than *Lot 4*, although the latter was well within the range of color of commercially canned tomatoes. *Lot 5* was slightly darker in color than *Lot 3*, the small untreated tomatoes. There was no evidence of any lycopin formation in *Lot 5*. We found a marked difference in the quantity of juice that could be expressed from the crushed fruit, depending upon whether or not the tomatoes had been treated with ethylene and also upon the stage of maturity. The average amount of juice obtained in three separate trials was as follows:

Lot 1, 71 per cent

Lot 2, 82 per cent

Lot 3, 62 per cent

Lot 4, 77 per cent

Lot 5, 70 per cent

VITAMIN A

Curative vitamin A tests were conducted essentially according to our technic as described elsewhere.²¹ In the first series four litters of rats showing definite signs of ophthalmia were divided into six groups, each consisting of 2 males and 2 females, 1 animal from each of the four litters. Five groups were fed 5 c.c. of tomato juice daily from each of the five lots of tomatoes as indicated by the figure to the left of each curve in Chart I. The remaining group served as a negative control. The A-deficient diet consisted of alcohol extracted casein, 18 per cent; salt mixture (Osborne and Mendel's), 4 per cent; agar, 2 per cent; yeast, 8 per cent; dextrinized starch, 67 per cent; and peanut oil, 1 per cent. Of the yeast used 0.5 per cent had been irradiated, and its vitamin D potency had been determined.

The tomato feeding was discontinued at the end of 5 weeks, and the animals were then kept on the basal diet until they showed considerable loss in weight. As shown in Chart I the rats which received the naturally ripened tomatoes, Lot 2, made distinctly better gains

than those of the other groups. The control rats survived an average of 23 days from the time their litter mates were first fed tomatoes, and all developed severe cases of ophthalmia before death. The other groups all showed improvement of the eyes during the tomato feeding period, but there were no definite cures of ophthalmia. The group receiving tomato juice, Lot 5, did not react differently from the other groups notwithstanding uniformly poorer growth. The sharp breaks in the curves when the tomato juice was withdrawn from the diet shows that the level of tomato fed did not permit storage of vitamin A.

The second series of tests was conducted in the same manner as the first, except that the tomato feeding was carried on for 8 weeks, and the experiment then terminated (Chart II). As in both series of tests the rats receiving Lot 2 tomato juice grew more rapidly than those on any other lot, it is evident that the naturally ripened tomato is the best source of vitamin A. No explanation is offered for the fact that in the first series the rats on Lot 5 did not grow so well as those of the other groups. There was very little individual variation within the group. In the second series the Lot 5 rats showed the largest average gain, with the exception of Lot 2, due to the exceptionally rapid growth of one animal.

At the end of 5 weeks the following average gains had been made in each of the ten groups:

	Lot 1	Lot 2	Lot 3	Lot 4	Lot 5
First Test	55	68	54	51	38
Second Test	54	60	52	53	53

VITAMIN B

In the vitamin B tests the following diet was used: Alcohol extracted casein, 18 per cent; salt mixture, 4 per cent; agar, 2 per cent; cod liver oil, 2 per cent; autoclaved yeast, 5 per cent; and dextrin, 69 per cent. The yeast was autoclaved 4 hours at 15 lb. pressure, and previous tests had shown it to be free from the antineuritic vitamin. The casein was similar to that used in the vitamin A tests just described.

In the first series of tests four litters of rats weighing about 60 gm. each were divided into six groups comparable as to size, sex, and parentage. One group received only the basal diet while the others received 5 c.c. per day of the different lots of tomatoes for a period of 60 days. Each curve for the first series seen in the upper portion of the chart shows the average weight increase of 4 rats, 2 males and 2 females. As shown on Chart III the fully ripened tomatoes, Lot 2, were distinctly superior as a source of vitamin B to the other lots, which were all about the same.

Each curve of the second series, begun nearly 3 months later, represents the average weight of 4 male rats. Not more than one animal from one litter was used in a group. In no case did the rats in the second series grow as rapidly as those in the first and there was not the same degree of response in comparable groups. The average gain for all the males in the first series (2 rats in each group) was 53 gm. The average gain in weight for all rats in the second series (all males) was 41 gm. Evidently a marked loss of vitamin B occurred in the canned tomatoes during the period intervening between the two series of tests.

The average survival of the control rats in the first series was 31 days and the second series 41 days. One of the controls in the

first series died at the end of 20 days, about 10 days less than the minimum survival period usually observed.

VITAMIN C

As in the vitamin A and B tests, the vitamin C assays were conducted on two sets of animals. In the first series the interpretation of the results is based upon symptoms of scurvy in the living animals and post-mortem examinations. In the second series, data on survival of the animals were also obtained. The two sets of experiments will be discussed separately. Twenty-eight guinea pigs weighing from 280 to 325 gm. were divided into seven equal groups, five of which received 1 c.c. of tomato juice from the different lots of tomatoes. The other two groups were used as controls. One group received 2 c.c. of orange juice daily, and the other served as a negative control. The basal diet consisted of rolled oats, 69 parts; alfalfa, autoclaved 30 minutes, 25 parts; casein, 5 parts; and sodium chloride, 1 part.

At the end of one month only one control animal showed definite symptoms of scurvy, and the other animals were all apparently normal, with the exception of a slow growth rate in many. Evidently our basal diet was not free from vitamin C. Alfalfa which had been autoclaved 90 minutes was then substituted for that which had been autoclaved 30 minutes. In 2 weeks all of the negative controls showed marked symptoms of scurvy, as did the two groups receiving tomatoes, Lots 3 and 5. Three animals in each of the groups receiving tomatoes, Lots 1 and 4, showed distinct signs of scurvy before the experiment was terminated. None of the animals receiving the naturally ripened tomatoes, Lot 2, nor those receiving orange juice showed any signs of scurvy. The only marked difference between these two groups was the more rapid rate of growth of the orange juice fed animals.

At the end of 58 days the animals were killed and post-mortem examinations made. The groups receiving tomato juice, Lots 3 and 5, and the negative controls all showed severe scurvy. Extensive subcutaneous hemorrhages, brittle bones, and frequently loose teeth were the most conspicuous findings. Three animals in each of the groups receiving tomatoes, Lots 1 and 4, showed subcutaneous hemorrhages, while the remaining animal in each group was apparently normal. Those receiving Lot 2 gave no post-mortem evidence of scurvy.

Before starting the second series of tests we demonstrated that the alfalfa we were using contained a considerable quantity of vitamin C and that if it were autoclaved 90 minutes the animals would develop scurvy in about 3 weeks. Consequently, the alfalfa was autoclaved 90 minutes in our later work.

The second series of tests on the tomato juice was conducted on the same number of guinea pigs, all virgin females, weighing from 250 to 297 gm. The levels of tomato and orange juice fed were the same as in the previous series. Because of the differences in vitamin C content of the various lots of tomatoes, we obtained data on the survival of the animals. At the end of 90 days when the experiment was terminated 7 animals were alive, 1 receiving Lot 1 tomato juice, 2 receiving Lot 2, and 4 receiving orange juice.

Table I gives the days of survival of the animals used.

TABLE I

<i>No Vitamin C</i>	<i>Lot 1</i>	<i>Lot 2</i>	<i>Lot 3</i>	<i>Lot 4</i>	<i>Lot 5</i>	<i>Orange Juice</i>
36	61	59	35	51	56	90
40	90	50	35	44	31	90
41	59	90	48	22	34	90
35	51	90	17	46	43	90

With the exception of the guinea pigs receiving orange juice and 2 animals receiving Lot 2 tomato juice, all of the animals showed unmistakable symptoms of scurvy at the end of 3 weeks. One animal on Lot 1 which survived the experimental period was inactive during the last 40 days, and showed complete loss of control of the hind legs. The 2 animals on Lot 2 which survived the experimental period remained active until the end. At times their wrists were sore and swollen, but scurvy symptoms were transient. Post-mortem examinations revealed evidence of scurvy in both of these animals. All animals which died showed severe scurvy upon post-mortem examination. The control animals all made a steady average gain of about 3 gm. per day until the experiment was terminated.

DISCUSSION

The most practically significant result is probably the evidence obtained showing that naturally ripened tomatoes are a better source of vitamins A, B, and C than any of the others studied, either treated or untreated with ethylene gas.

No material difference was observed in the vitamin A content of the green tomatoes picked at different stages of development, whether or not treated with ethylene. The same was true of the vitamin B content of the different lots as determined in the first series of tests.

The vitamin C value of tomatoes seems to increase as the fruit develops and approaches the mature ripened condition. Naturally ripened tomatoes contained the most vitamin C, full grown, green tomatoes came next, and the small, immature fruit contained the least of all. The ethylene treatment of the green tomatoes produced no

significant change in their vitamin C potency, which was low in all samples of the green fruit tested. The second series of tests for vitamin B gave lower values than obtained in the first series with samples of the same lots. Apparently a loss of this vitamin occurred on storage, for which we have no explanation.

After the work described was well under way, two articles on this subject appeared. Morgan and Smith¹² found that ripe tomatoes were richer in vitamin A than green tomatoes, but that the amount in ripe tomatoes was about the same, irrespective of the methods used in ripening. House, Nelson, and Haber¹³ found that green and ripe tomatoes contained essentially the same amount of vitamin B, irrespective of the methods used in ripening. They also found more vitamin A in ripened than in green tomatoes, but the tomatoes ripened by the different methods had the same amount. Their results on vitamin C are in agreement with ours. Our results cannot be satisfactorily compared with those of House, Nelson, and Haber, because these authors fed the whole tomato, while we fed only the juice. Furthermore, they do not give sufficient details regarding the handling of the tomatoes after having been picked from the vines, and they make no statement regarding the length of time the tomatoes were treated with ethylene.

In so far as the use of tomato juice as a source of vitamins is concerned the results of our work indicate that vine-ripened tomatoes are preferable to those picked green and treated with ethylene gas to develop the color characteristic of ripe fruit. No indication was observed that the ethylene treatment had any deleterious effect upon vitamins already developed.

Seasonal Distribution of Typhoid Fever—Southern and Northern States*

G. E. HARMON, M. D., F. A. P. H. A.

Department of Hygiene and Bacteriology, School of Medicine, Western Reserve University, Cleveland, O.

MANY diseases exhibit a marked seasonal variation in their incidence, a phenomenon of perpetual interest to epidemiologists. Recently some evidence has been brought forward which indicates that this phenomenon may depend to some extent at least upon periodic changes in immunity caused by seasonal variations in the physiological activities of the human body. Aycock¹ has discussed the differences observed in the incidence of poliomyelitis from this point of view and suggests these may depend upon variations in human physiology rather than upon variations in the virus. Experimental studies carried out by Arnold^{2,3} on dogs indicated that the secretion of hydrochloric acid by the stomach was diminished when the external temperature was high. This in turn was found to disturb the acid-base equilibrium of the upper part of the small intestine, with the result that the "self-disinfecting" power of the mucous membrane was reduced, as shown by the fact that the duodenum no longer had its usual ability to destroy organisms introduced into it. In this instance also variation in immunity seems to be due to variation in physiological activity. Arnold points out that in view of his experimental studies it would be expected that typhoid fever would be more prevalent in summer than in winter, a deduction which agrees with epidemiological experience. The greater prevalence of typhoid fever in summer may thus be ascribed to the heat associated with that season.

These explanations suggested that it would be of interest to compare the seasonal distribution of the yearly incidence of typhoid fever exhibited by southern states with that by northern states.

Since it had been shown⁴ that for measles, diphtheria and scarlet fever the peak of the incidence for each occurs a month or two earlier in the southern than in the northern states, and since the southern part of the United States experiences a high temperature earlier in

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

the summer than the northern, it was decided to see whether there was any difference in the time of the maximum occurrence of typhoid fever in these two sections. Time series representing the occurrence of typhoid fever by months over a period of years (1912-1928) for a number of states were studied and for each successive complete seasonal swing or wave of a series the month of maximum incidence was noted. A month of maximum incidence is the month within the limits of one complete seasonal swing or wave for which the maximum number of cases is recorded.

No state was used for which adequate data had not been published in the Annual Summaries of the Notifiable Diseases appearing in *Public Health Reports*. In order to have as much separation in latitude as possible between a group of southern and a group of northern states, Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina and Tennessee were included in the former, and Connecticut, Maine, Massachusetts, Michigan, Minnesota, Montana, North Dakota, New York and Wisconsin in the latter.

For the former group July, while for the latter group September, was most frequently the month of maximum incidence. In other words, by the method used, the peak of the incidence of typhoid fever

for the states studied was shown to occur two months earlier in the southern than in the northern group. The frequency distribution of the months of maximum incidence obtained for each group of states is presented in Table I and Figure I.

By this method of analysis only the month of maximum incidence of any individual seasonal wave was considered. Furthermore, the experience of all years was included without regard to whether they were epidemic or non-epidemic in character. In addition to the information which this approach furnished, it was desirable to ascertain the characteristics of a typical seasonal wave derived

from the data of the southern states and also of one from the data of the northern states. Both of these were needed in order that a comparison might be made as to the distribution of cases by months throughout an entire year. A number of such seasonal waves or curves were obtained by various methods.

To insure that each wave or curve would be based upon a sufficient number of cases to give some degree of stability to the result, the figures representing the monthly incidence were combined. For the nine southern states the total number of cases of typhoid fever during the period 1912-1928 was obtained by simple addition. The total number for each month was obtained in the same way and expressed as a percentage of the grand total. A similar procedure was followed for the nine northern states. The percentage seasonal distribution of cases for each area appears in Table II and Figure II. A comparison of the two curves clearly indicates that typhoid fever reaches its maximum earlier in the south than in the north. Certain objections, however, can be legitimately raised to percentage seasonal distributions of cases thus derived. Data for each year of the entire period of seventeen years were not available for every state; the method assumed that a typical distribution could be obtained by using the arithmetical mean, and the degree to which the result might be affected by the weight of a large state was undetermined.

To deal with these objections and to test the reliability of the derived seasonal curves, a different procedure was tried. A southern combined area was formed which included Alabama, Louisiana and Mississippi; and a northern one which included Connecticut, Michigan, Minnesota, New York and Wisconsin. The composite monthly incidence of typhoid fever for each area was next obtained by adding together for the included states all the figures representing the in-

FIGURE I—Typhoid fever. Frequency distribution of 100 months of maximum incidence

cidence of corresponding months. This method of combining numbers of cases and the fact that the composite monthly incidence of the two areas was to be compared by means of averages, as explained below, required that data for each and every state, without regard to the area in which it was included, must be available by months over the same period of time. The limitation to these states and the period 1915-1928 was dictated by this requirement.

FIGURE II—Percentage seasonal distribution of typhoid fever for a year of mean incidence calculated for the period 1912-1928

TABLE II

Dec.	4.15	6.61

The next step was to obtain for each area the incidence of a typical year distributed by months, really a seasonal wave. The experience of any given year, because of the irregularities it might exhibit, was considered unsatisfactory and therefore the incidence of a typical year was calculated from the recorded experience of all the years in the period considered. Two methods of calculating the incidence of a typical year were employed—one based upon the median as an average, a full discussion of which appeared in a recent article,⁵ and the other upon the arithmetical mean as an average. The former was carried out as follows: For each combined area the figures representing the incidence of typhoid fever for all the various included Januarys were placed in an array and a central value corresponding approximately to the median was determined by means of a parabolic smoothing, and a similar method used for each of the other months. These twelve monthly median numbers of cases were added together to obtain the total for a year of median incidence. The median incidence of each month was expressed as a percentage of this total, the

twelve resulting percentages being an expression of the seasonal distribution of the cases in a year of median incidence.

In obtaining the incidence of a typical year based upon the arithmetical mean as an average, the mean of each array was calculated instead of the median. The twelve monthly mean numbers of cases were added together and the mean incidence of each month expressed as a percentage of this total.

Table III reveals that both procedures gave approximately the same result. In other words, the arithmetical mean turns out to be a suitable average to use in calculating the incidence of a typical year. Furthermore, a comparison of the seasonal distributions thus derived for the two combined areas (see Table III and Figure III) confirms the observation that the peak of the wave for the northern area occurred two months later than that for the southern area. There is also some slight though inconclusive evidence that the wave for the southern states is less peaked than that of the northern.

Table IV shows that each state exhibited in a general way the same seasonal distribution as the combined area to which it belonged. The results, therefore, which had been obtained were not due to the effects of one large state, in other words, to weighting.

An attempt was made to determine whether there had been any tendency for the seasonal distribution of cases to change with the passage of time. For the first three years and the last three years of

the period 1915-1928 percentage seasonal distributions of cases were calculated. Because it had been found that computations based upon the mean gave results quite comparable to those based upon the median, the method just outlined—making use of the arithmetical mean—was employed. The results for both combined areas are presented in Table V, Figures IV and V. The percentage seasonal distribution of cases for each area has remained quite constant although there has been a marked decline in the incidence of typhoid fever. This is in agreement with Mills's⁶ observation that over quite a long period

FIGURE IV—Percentage seasonal distribution of typhoid fever for a year of mean incidence calculated for three combined southern states

FIGURE V—Percentage seasonal distribution of typhoid fever for a year of mean incidence calculated for five combined northern states

there had been no change in the seasonal distribution of typhoid fever deaths in certain cities.

The incidence of typhoid fever per 100,000 population is much higher in the southern part of the United States than in the northern. The question arose as to whether the seasonal distribution observed

in the southern area might not be related to this concentration of cases. To investigate this point the seasonal distribution of the northern combined states for 1915-1917 associated with an incidence rate of about 4.6 was compared with that for the south-

ern combined states for 1926-1928 associated with an incidence rate of about 7.7. Table V, columns 3 and 4, together with Figure VI, further suggests that there is a distinct difference between the percentage seasonal distribution of cases for the two respective areas.

SUMMARY AND DISCUSSION

A comparison of the seasonal distribution of typhoid fever in certain of the southern and certain of the northern states has been made.

Evidence has been presented which indicates that for each latitudinal group the seasonal distribution of typhoid fever has not changed with the passage of time even though there has been a marked decline in the incidence.

Some evidence has been brought forward which tends to show that the seasonal distribution of typhoid fever is independent of the incidence rate.

It has been shown that each group has a distinct seasonal distribution.

The conclusion seems justified that the curve of the seasonal distribution of typhoid fever cases for the southern states differs from that for the northern states in reaching a maximum earlier, and in exhibiting a slight tendency toward a greater proportionate concentration of cases during the hot months of the year. This would seem to imply that there are forces favoring typhoid fever which operate during the hot part of the year with greater intensity and over a longer period of time in the south than in the north. Since the southern section experiences a high temperature earlier in the year than the northern, and since the period of high temperature lasts longer, the difference observed is what might have been expected if high external temperature were responsible for the greater prevalence of typhoid fever in summer.

Study of the seasonal curves for southern states or areas (Figures II, III, IV, V and VI) reveals the fact that they start to decline while the temperature is still high. How is this to be explained? Arnold's studies^{2,3} suggest the possibility that after a period of exposure to a high temperature the body gradually adapts itself to this external condition, with the result that the altered defensive mechanism of the intestinal mucosa again becomes normal even before the advent of cold weather can produce any restorative effects, and that possibly the influence of high external temperature may be offset toward the latter part of the summer by changes in diet. While differences in the distribution of temperature between the southern and northern sections, either as it affects the human body, or perhaps the means of transfer, may be responsible for the observed differences in the seasonal distribution of typhoid fever, the effects of other possible variable factors such as moisture and ultra-violet radiation may need to be considered before a conclusion is reached.

Value of the Newly Identified Types in the Study of the Epidemiology of Pneumococcus Infections*

WILLIAM H. PARK, M. D., F. A. P. H. A.

Director of Laboratories, Department of Health, New York, N. Y.

THE early work on pneumococci disclosed the fact that they did not all belong to the same immunological type. In this country and Europe, Types I, II, and III were isolated and preserved. In adults in New York and vicinity between 50 and 60 per cent of all pneumonia cases were found to be due to these types. The remainder were gathered together as Group IV. These pneumococci, however, did not really form a group. They were simply those which had not been classified, as I, II, or III. This separation of the three main types was most valuable, but the impossibility of identifying about one-half the pneumococci from cases of pneumonia in adults and two-thirds of them in young children, was a great drawback in detecting the spread of infection, and appreciation of this stimulated further investigation. Very briefly the history of the separation of additional specific types is as follows:

In 1915, Avery¹ separated from characteristic Type II pneumococci two sub-types which differed immunologically from each other and from Type II. A year later Lister² noted that in South Africa the most frequently occurring strain was of a type different from I, II, or III. Olmstead in New York during the same year made a study of 213 distinct strains of pneumococci and classified them into 12 immunological groups. Cooper³ and Mishulow in 1919 and 1920 differentiated 19 types. Griffith⁴ in 1922 studied 49 strains, none of which belonged to Types I, II, and III. He distinguished 12 distinct serological types. Robinson⁵ in 1928 in Pittsburgh noted that in all the cases occurring in a localized outbreak of pneumonia in that city, only 1 type of pneumococci was obtained, and this was not I, II, or III.

These and other researches indicated the need not only of separating the Group IV pneumococci as far as practicable into the several types comprising it, but also of preserving the type strains, and for the

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

different types, a specific serum for each. The possession of the cultures and their specific serums would make it possible not only to utilize them to identify newly isolated pneumococci, but also to send them to other laboratories, so that the presence and frequency of any of these types in any other parts of the world could be determined. There would of course be other uses of these additional preserved types, such as determining their seasonable variations and estimating the curative value of a specific antibacterial serum for each.

After a conference, Cooper in 1927 decided to undertake this work. She has now identified, and has in her collection, cultures of 17 additional types. The majority of what would have previously been unclassified pneumococci can now be identified. Many interesting facts have been developed. Thus the pneumonia cases in adults and children in Bellevue and Harlem Hospitals have been typed, and we have noted the relative occurrence of the different types. Up to the end of 1928, she had only 13 types fully worked out. For each of these she had a specific agglutinating serum. Before referring to the results obtained it is necessary to note that Westlung⁶ and others had noted a much larger percentage of Group IV pneumococci in the pneumonias of children than in those of adults.

Westlund's tabulation of the reports of others is shown in Table I.

TABLE I

TYPES OF PNEUMOCOCCI IN PNEUMONIA

	Adults (1,552 Cases) per cent	Children (401 Cases) per cent
Type I	36.0	26.0
Type II	28.0	11.0
Type III	13.0	8.0
Group IV	23.0	55.0

Cooper's own investigations on the pneumonias of children yielded most interesting results (see Table II).

Turning to the results obtained in the Laboratories of New York and Cornell Universities in our own investigations we find the same general distribution of Types I, II, and III and Group IV, but now we have the added interesting information as to the distribution of a considerable percentage of the pneumococci into 10 other types, and of the differences of the percentages of each type not only between adults and children but also between older and younger children.

Before giving an example of the value of the possession of specific

TABLE II

INCIDENCE OF PNEUMOCOCCUS TYPES IN CHILDREN

No pneumococci	11.8	30.4	7.6	41.6

serums for each of the newly established types in detecting an outbreak due to one of them, let us consider the stability of types.

It has been long established that the majority of people in cities carry pneumococci in their throats. These generally belong to the unclassified or Group IV strains. Now we realize that Group IV is simply the lumping together of a number of types, each of which is represented in adults by a smaller percentage of pneumococci than Types I, II, and III, but in children some of these predominate. Each of these types is just as clear-cut as I, II, and III.

TABLE III

* Material from children obtained by Raia and typed by Schultz in the laboratories of Cornell University. Adult material typed by Cooper in the Research Laboratory of the Health Department.

Are the types of pneumococci fairly permanent, or are they constantly shifting? Griffith, in England, believes that they readily change and that this frequently happens at the time of convalescence. The results of our own researches agree with those of earlier investigations. Stillman found that during and after convalescence, the type of pneumococcus persisted for many days. In 53 cases of lobar pneumonia the shortest period in which the specific type persisted was 7 days, and the longest 85 days. Under natural conditions we expect therefore that a pneumonia due to a definite type of pneumococci will disseminate this type to others.

Let us now turn to a striking instance when one of the new types was responsible for an outbreak of pneumonia in an institution and in all probability of colds as well. Without a specific serum on hand the cause of the outbreak would have escaped us.*

In an institution for the care of about 700 children between 3 and 16, equally divided between boys and girls, an epidemic of colds and pneumonia occurred. This developed among the boys with the exception of one girl. The outbreak occurred first among the younger children and then among the older who were in contact with them, and then among those of all ages. Schroder, who has charge of the immunization of the children against diphtheria and scarlet fever, happened to learn of the epidemic just as it was beginning to abate. She gathered as much data as possible as to the method of spread of the disease, and obtained culture material on swabs from the pharynxes of 9 cases. From this material Cooper obtained in 7 cases pneumococci which were found to be Type V of our new classification. The onset of the cases was characteristic of a local epidemic of a communicable disease. Within 10 days of the development of the first case the peak occurred. On one day 34 cases developed. The outbreak then rapidly declined. Of something over 100 children who were sick, 30 per cent had pneumonia. The others had symptoms and physical signs of either bronchitis or common colds. While all the 7 positive cultures were from cases of pneumonia, we have no doubt the cases of bronchitis and colds were also due to the pneumococcus, since there were all gradations in severity from the mildest cold to a fully developed pneumonia, and the different severities of the disease occurred proportionately throughout the attack. If Cooper had not had a specific agglutinating serum for the type there would have been no probability of working out the relation of the pneumococcus to the

* The full account of this outbreak, by Schroder and Cooper, will be printed in an early number of the *Journal of Infectious Diseases*.

outbreak. Through having accessible the specific serums for these added types, we have increased our chances of gaining valuable knowledge concerning the spread of pneumococcus infections, especially among children.

Antiseptics

THE old adage, "There is nothing new under the sun," is constantly being emphasized. In a recent publication,¹ there occurs an interesting discussion of the words "antiseptic" and "asepsis," which are generally considered to be of modern origin, yet "antiseptic" is found in medical literature in the middle of the 18th century, and was commonly used by the laity.

In the "Gentleman's Magazine" (1751) we find the statement, "Myrrh is twelve times more *antiseptic* than sea salt." St. Blancard's lexicon (1777) contains the following definition: "Antiseptica, sunt remedia interna et externa, quae putridini resistunt." According to Ebstein, the use of gloves in obstetrics was advocated in the year 1758.

An interesting letter by George Foster,² written in 1791, says: "I had no desire to eat, etc.—all the symptoms of a general breakdown. Drank quantities of vitrol acid and ate kraut conserve. In short I was kept *antiseptic* and after a few days I became better. I now felt hollow and empty and very weak on my legs."

Semmelweis and Lister both brought forward what we now call antiseptics, using sodium chloride, chloride of lime, alcohol, etc. The surgeons of that day seemed to use antiseptics with the idea of rendering decomposition harmless, but Semmelweis, who used them on his hands to prevent infection, said: "You should work with clean hands." Fleetwood Churchill said: "A gentleman's hands are clean."

An interesting sidelight is thrown on the slow acceptance of Lister's teaching in England. It was explained that the Germans were known as a dirty people, and therefore antiseptics might be necessary for them, but in England, they were superfluous. It was not necessary there to demand the cleansing and disinfecting of the finger nails because a "gentleman cleans his finger nails in his sleeping room."

Public Health Nursing Legislation What It Should Include*

MATHILDE S. KUHLMAN, R. N., F. A. P. H. A.

*Director, Division of Public Health Nursing, New York State Department
of Health, Albany, N. Y.*

LAWS governing public health nursing have been enacted in the majority of states, Massachusetts and Pennsylvania having been the first to pass such legislation in the year 1911. Since then laws have been placed upon the statute books nearly every year, and some of them have been repealed.

Many general health laws include public health nursing and provide for the employment of nurses, sometimes defining the type of work to be done, such as child hygiene, tuberculosis, school nursing, or other specialized work to which nurses are assigned. It is not intended here to give a résumé of the various state laws governing public health nursing. Such information may be found in *A Review of State Laws on Public Health Nursing* by James A. Tobey.¹

In that study it is noted that there are no standard requirements; the territory covered may be state, county, city, town or village, or may not be designated. The duties in some instances apply to specialized work, or they may not be definitely defined; supervision is vested in the state commissioner of health, a health officer, county commissioners or county supervisors, school boards of trustees, or city or town councils, or no specific body may be mentioned to whom the nurse is responsible. In some state laws professional qualifications are outlined and in others none are mentioned.

It is realized that conditions vary in different parts of the country, which might make it seem to some that no standard regulations would be universally applicable. There are certain fundamental principles applying to public health nursing which were recognized as essential in the very earliest days of visiting nursing. The first and most important are that nurses shall be well prepared for the work, and that adequate supervision shall be provided. Some apply to the observance of professional etiquette, coöperation with other workers and

* Read before the Public Health Nursing Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

agencies, the importance of accurate records, and others as defined in *Public Health Nursing*, by Mary Gardner.

These principles have been adhered to wherever successful work has been engaged in, and will without doubt apply for all time everywhere.

It is assumed that the state is interested in recognizing the professional ability of the nurse as a community worker and that it desires to protect the public from untrained workers, and guard the profession against unskilled competition. The objectives in legislation governing public health nursing are:

1. To secure for the public the graduate nurses best prepared and otherwise qualified for public health work
2. To provide for the worker the best conditions under which to carry on the work

Legal standards should be minimum standards, and sufficiently flexible to provide for future developments in order to avoid frequent changes in the law which may lead into unforeseen difficulties. Good public health nursing laws should provide for the following:

1. The creation of a bureau or division of public health nursing in the state department of health, headed by a nurse director appointed by the state commissioner of health
2. The statement of minimum qualifications required for all public health nurses
3. The power of appointment by local authorities
4. The definition of duties
5. The creation of an advisory board or nursing committees

The director of such a bureau or division should meet the requirements as outlined by the National Organization for Public Health Nursing. She should have a good educational and professional background, be a worthy representative of her profession, and be familiar with all phases of nursing in her own state. She should have the power to develop her work, as other heads of divisions do, and a free hand in selecting personnel. She should be able to prepare and advise on budget requirements, salaries and travel expenses for staff nurses, clerical help, and equipment.

The purpose of a division or bureau of public health nursing is to educate, organize and standardize the service in the state; to supply qualified nurses to other divisions of the department; to meet qualifications set by the state department of health; to define duties broadly to include all branches of public health nursing; and to aid in securing the appointment of nursing committees representing public officials, representatives of medical societies and lay persons interested in or sponsoring the service.

A roster of public health nurses in the state (by counties) giving name, address, type of work, salary and preparation of nurse, and previous positions held, should be readily available for study and comparison, and other nursing information should be on file in good form.

In New York State the law created in 1913 states that there shall be a division of public health nursing in the State Department of Health, and the Public Health Law permits the Public Health Council (an advisory body) to prescribe the qualifications for public health nurses as also for health officers. This seems desirable to meet frequently changing requirements without continually enacting or repealing laws.

Such a division or bureau should—

1. Furnish advisory, supervisory or consultant service and conduct demonstrations
2. Place nurses and aid them in maintaining good standards
3. Provide record and report forms and supervise their use
4. Coöperate at all times with state and local agencies who are carrying on public health work, whether employed from public or private funds

For staff and for local appointment, nurses should meet the requirements of the nurse practice act in their own state and be qualified for public health nursing according to standards set by their state department of health. Legislation should permit local boards of health and education to employ nurses in cities, towns and villages.

The duties should be broadly outlined, covering the general phases of public health work, such as maternity, infancy and child hygiene, tuberculosis, social hygiene, communicable diseases, school nursing, and bedside care as needed in emergency.

The Public Health Law of New York State, Article III, reads as follows:

Each health officer or other official exercising similar duties, by whatever official designation he may be known, shall have power to employ such number of public health nurses as in his judgment may be necessary within the limits of the appropriation made therefor by the city, town or village. They shall work under the direction of the health officer and may be assigned by him to the reduction of infant mortality, the examination or visitation of school children or children excluded from school, the discovery or visitation of cases of tuberculosis, the visitation of the sick who may be unable otherwise to secure adequate care, the instruction of members of households in which there is a sick person, or to such other duties as may seem to him appropriate.

This seems to be inclusive of all duties to which a nurse may be assigned.

Legal provision for the appointment of an advisory council or public health nursing committee is a wise requirement. Such a committee should consist of members of the official body which employs

the nurse, representatives of the local medical society, preferably health officers, and lay persons who are interested in the progress of public health nursing or those who have previously sponsored the work, such as members of the nursing committees of the American Red Cross or representatives of civic and church organizations. Such a committee would be an important factor in avoiding political appointments of nurses and in other ways giving morale to the work.

What board members can do for the work was ably defined by Michael M. Davis, Ph.D., in an address on "Functions of Boards of Trustees and Committees," given at the American Nurses' Association Meeting and Institute for Board Members.*

Ten Duties for Board Members—

1. To know why the organization exists and annually to review why it should
2. To govern a board or a committee through joint thinking, not by majority vote
3. To give money, or help get it, or both
4. To face budgets with courage, endowments with doubt, deficits without dismay, and to recover quickly from a surplus
5. To deal with the professional staff as partners
6. To keep far enough ahead of the community to be progressive, and close enough to it to be practical
7. To interpret health work to the public in words of two syllables
8. To deal with physicians on the assumption that the highest ideals of the profession dominate its every member and to face difficulties with recognition that both doctors and board members are human
9. To be proud of a tradition but eager to improve it
10. Always to combine a New England sense of obligation with an Irish sense of humor

When public health nursing legislation is proposed to be introduced in a state, a lawyer's advice should be secured. It is wise to give careful thought to the wording, defining the minimum requirements and making the law sufficiently flexible to allow for the constant expansion in public health activities.

ANTIRABIC TREATMENT PARALYSIS

THE appearance of paralysis during and following the administration of antirabic vaccine is one of the accidents which we must recognize as inherent in the preventive treatment. Fortunately, its occurrence is rare, but unfortunately, the etiology is unknown, in spite of the study which has been devoted to the matter.

The explanations given have not been satisfactory. Some have held that it was due to a dose of the street virus which without the vaccine would have proved fatal, and others that it was directly due to the fixed virus. Busson holds that under certain conditions the fixed virus may become neurotropic, and lays stress on the presence of fixed virus in the nervous system of those who succumb. Tinti considers it an anaphylactic phenomenon. Harris feels that individual susceptibility to rabbit brain is the chief factor. It is now widely believed to be due to the action of some unknown substance contained in the vaccine. We can only accept the statement of the Rabies Conference that our knowledge does not enable us to make positive assertions as to the etiology.

Among the predisposing causes, alcoholism, syphilis, neuropathic constitution, cold, fatigue, and overwork were mentioned at the International Rabies Conference in 1927, at which Remlinger presented a study of the accidents following vaccination against rabies in Pasteur Institutes which covered practically the entire world.

In the vast majority of cases, the injection of living fixed virus vaccine is harmless. Paralytic accidents are less frequent when glycerinated or carbolized vaccines are used, and for this reason, some insti-

tutes have adopted the use of dead or attenuated material, though cases have followed the use of all methods. Those affected are most commonly between 20 and 60 years of age, and belong to the intellectual professions, comparatively few cases occurring among the natives of tropical countries and children. The intensive treatment is more often followed by paralysis than the regular.

In view of the facts, the Pasteur treatment should not be advised without a careful consideration of all the circumstances. On the other hand, since its protective value is undoubted, and wonderful results have followed its use, it should not be withheld from an exposed patient without good reason. With a definite diagnosis of rabies in the biting animal, and a wound, there should be no hesitation in giving the treatment. The International Rabies Conference was equally divided as to the necessity of treatment of persons with whose skin the saliva of a rabid animal had come into contact, even when there was no visible break. The number of deaths from post-vaccinal paralysis is about 100 times that of cases of hydrophobia due to the licking of the skin by rabid dogs. When the mucous membrane was contaminated in this manner, the great majority advocated the Pasteur treatment.

In certain cases, it seems advisable to keep the patient at rest in bed, but the large number of patients who take the treatment at home and pursue their ordinary avocations without bad results, indicates that this measure should be taken only in extreme cases.

The number of cases of paralysis varies, but in all series reported, the percentage is extremely small, and fatal cases are rare.

Remlinger gives the percentage of cases as 0.28 per 1,000, or 1 for every 3,538 persons treated. When symptoms appear during treatment, as they do in about two-thirds of the cases reported, the injections should be discontinued, and the patient put at rest. The reports of two recent cases,¹ one fatal, and one ending in recovery, describe the symptoms and give additional facts.

HOW MUCH TOXIN-ANTITOXIN IS NECESSARY

THE Michigan Department of Health has made exhaustive studies on the amount of toxin-antitoxin work necessary to rid a community of diphtheria. While this varies widely, depending upon density and age distribution of the group immunized, some generalizations are evident.

The department has been furnishing toxin-antitoxin free of charge for a period of 6 years. The counties, cities and smaller districts that

have immunized ten times as many persons as are born in a single year have had no diphtheria. A number of the more progressive cities and districts have accomplished this in 5 years by immunizing children to the extent of approximately double the number of births each year. After the first 5 years of this intensive work, the community can be kept free from diphtheria if the number of persons immunized encompasses the number of births. The only proviso is that the work be carried on in the preschool group, with the objective that every child be immunized as soon after 6 months of age as is possible.

This experience seems to be sufficiently widespread to be considered a reproducible phenomenon. As a result, the Michigan Department of Health is using as a standard the cities and communities where diphtheria has been made "ancient history" by immunizing each year for a period of 5 years a number of persons equivalent to twice the number of births, and thereafter campaigning for the immunization of all children as soon after 6 months as possible.

FORENSIC BLOOD TESTS

BECAUSE the health department has a laboratory and because the material studied is biological in character, the health officer is often expected to furnish not only laboratory service but expert opinion on many phases of forensic medicine. Such matters are primarily police problems, yet both law and custom have made them a duty of the health department. With many of these examinations the results are sufficiently definite to cause no particular hesitancy in accepting and reporting them, but when blood is involved, the health officer as an expert witness finds himself in difficulty unless he has had considerable experience and is more or less familiar with the literature on this subject.

The so-called blood tests are of two kinds, those to determine the kind of blood in evidence, and those concerning paternity. The technic of both is sufficiently well known and perfected, although with each the greatest care is necessary to prevent errors and to secure controls. If there is any popular opinion about these tests it is that with the first the technic is involved and the interpretation simple, while in the second (paternity tests—involving blood grouping) the technic is simple and the interpretation difficult. The literature, however, reveals the fact that in any case the method is by far the more significant. In attempting to determine the source of an unknown blood specimen, the method of doing that particular test is most important. In so far as paternity tests are concerned, the technic upon which the theory of inheritance itself rests must be taken into account.

If there were no questions of technic there would be little difficulty in determining the correct theory of inheritance.

The methods for performing precipitation tests upon blood the source of which is to be determined are well described in numerous textbooks of serology and forensic medicine. It is not necessary to consider this question further, except to add that Lattes (1927)¹ reported a type of investigation which may develop sufficiently to give much greater value to such tests. This investigator introduced a method for determining the group of the unknown blood in cases where it proved to be of human origin. Thus it may soon be possible to exclude certain individuals from connection with a given investigation or more definitely to involve another.

It is in testifying to paternity that the health official finds the most uncertainty and hence the greatest difficulty. The whole problem has been reviewed by Snyder (1927). It is concerned chiefly with the question of method of inheritance of the Mendelian factors. The fact that blood groups are subject to Mendelian inheritance is generally accepted, but there remains the problem as to whether two pairs of independent Mendelian factors (iso-agglutinogens A and B dominant to their iso-agglutinins a and b) or a series of three multiple allelomorphs (A and B dominant and O recessive) are inherited. In so far as the first three groups O, A, and B (or I, II, and III Jansky) are concerned the possibilities are identical regardless of which of the two theories is accepted. When either parent is of group AB (IV Jansky), however, the interpretation depends upon the theory accepted.

According to Snyder the theory of multiple allelomorphs is confirmed by the facts, yet for medico legal purposes it would seem unwise to accept this premise until it has been more definitely estab-

A + B	O, A, B, AB

lished. On the other hand, the results, with which both theories accord, are sufficiently proved to warrant their legal application. As a matter of fact in certain countries, notably Germany, blood grouping is assigned a definite place in legal procedure, and the qualification of expert witnesses as well as the extent of the value of their testimony

is definitely fixed. It would appear that in the United States blood groupings might be more extensively used as evidence with the understanding that all parties, from judge to witness, accept the more or less tentative value of the report. As a support to other evidence the results of blood grouping are of value. As a proof of an existing condition, it might cause injustice.

TABLE II

FIRST INTERNATIONAL CONGRESS ON MENTAL HYGIENE

AN unusual meeting will occur in Washington, D. C., May 5 to 10. This is the First International Congress on Mental Hygiene. From nearly all European countries, from several South American countries and from Japan and China, delegates will attend.

One reason why this will be an unusual gathering is that, for the first time in history, people who are interested in mental hygiene from many different angles will meet together to discuss common or related problems. There have been meetings of physicians interested in the care and treatment of the mentally sick. There have been gatherings of educators at which mental hygiene was discussed. There have been congresses of both doctors and nurses, with some attention paid to psychological factors in etiology and treatment. There have been meetings of criminologists, in which mental factors as causes of crime were thoughtfully considered. But here all these groups, and many others, will be present. The common interest of these numerous participants will be the recognition that mental and emotional conditions are important with respect both to disease and to conduct, and that teacher, physician, parent, nurse and many others share the opportunity to promote positive mental health as well as to avert nervous and mental disease.

Dr. Haven Emerson wrote some emphatic words about preventive measures in health fields, which apply as forcefully to the field of mental health as to that of physical health:

May I be permitted to suggest that it takes a higher type of intelligence, a greater faith, a truer sense of perspective, to foresee the approach of disease and protect against it, to see the enemies of health from afar; go out to meet them, outmaneuver them, outflank them, and down them by counter-attack, than to heal or tend existing disease? . . . We have arrived at a point in the organization of our national effort for health where advances in the fields already preëmpted and liberally supported by public opinion and resources must wait for their entire success upon a fair beginning and progress in the most delicate and difficult and yet the most promising undertaking of all—the prevention of nervous disorders and mental defects.

Health officers do not always see clearly what function they have in relation to mental hygiene. Some specific suggestions from Dr. Frankwood E. Williams, medical director of the National Committee for Mental Hygiene, bear on this question:

In considering, therefore, the future development of organized mental hygiene work in this country looking to the prevention of nervous and mental disorder, of delinquency, social inadequacy and dependency, it is apparent (1) that the public health officer in his epidemiological work contributes directly and importantly to one phase of mental hygiene work; (2) that in his attack upon the incidence of syphilis and his campaigning for the adequate, early treatment of those infected with syphilis, he contributes again in a very direct way to an important aspect of mental hygiene; (3) that in his campaign of education for the maintenance of better physical health generally, he contributes to that part of mental hygiene concerned with the prevention of nervous and mental disorders due to physical deterioration; (4) that the prevention of those disorders, personal and social, which are dependent upon the emotional and intellectual qualities and training of the individual, does not lie clearly in any one professional field, such as that of the public health officer, but must be accomplished through the professional coöperation of various groups, particularly those who have to do with the activities of children.

Every day the work of the health officer, the general practitioner, and the nurse is made easier and more effective because their patients, their patients' families and the communities in which they labor are intelligent and coöperative. Mental hygiene aims at intelligence and coöperativeness on the part of all men. To physician and nurse the issues of mental health, mental illness and mental invalidism are vital. We are sure that the proceedings of this Congress will prove interesting to our readers; some doubtless will attend, others will read the published reports.

President Hoover has accepted the position of Honorary President of the Congress.

NOTE: Information about it may be obtained from John R. Shillady, Administrative Secretary, 370 Seventh Ave., New York, N. Y.

Panorama of the Business Section

HISTORY OF FORT WORTH

VAST changes have been wrought in most American cities during the past thirty years, but in few have these changes been more spectacular and revolutionary than in Fort Worth.

The census of 1900 showed a total population of 26,688. The tallest building in the city was eight stories in height. But Fort Worth was served by an electric street railway, having electrified its lines in 1888, the first American city to do so.

If the town was small, it contained big men. They were truly giants in those days. Living on the frontier, far from the centers of population, they were fully impressed with the importance of adequate transportation. At tremendous sacrifices they raised bonuses of cash and lands that by 1900 had brought to Fort Worth the Texas & Pacific, The Fort Worth & Denver City, The Gulf, Colorado & Sante Fe, The Missouri, Kansas & Texas, The Houston & Texas Central, The Fort Worth & Rio Grande, The St. Louis-Southwestern, and The Chicago, Rock Island & Gulf railroads. Fort Worth

became and has remained the most important railroad center southwest of Kansas City.

It was the foresight of the pioneers in reaching out for the railroads that made possible the tremendous growth that Fort Worth has experienced. With a preferential trade territory in West Texas that is larger than the states of Illinois, Indiana and Ohio combined, Fort Worth had lagged for the reason that distances were so great and the population of her territory so thinly spread that it was an unprofitable area to serve.

But the turning point had been reached. In 1902 the Armour, Swift, and Libby, McNeill & Libby packing houses were built, representing an investment of more than \$10,000,000. They became the largest industrial group in the Southwest. With the stockyards company, the horse and mule dealers, livestock commission men and allied industries they today employ more than 5,000 persons.

The building of the packing houses brought a great influx of new popula-

Fort Worth, Texas

THE 59TH ANNUAL MEETING CITY

tion and lent a stability to the community, making it the center of the packing industry for the Southwest. Between 1900 and 1910 Fort Worth's population increased from 26,688 to 73,312.

The outstanding event of the next decade in Fort Worth's history was the establishment in 1917 of Camp Bowie, on the western boundary of the city. At the same time Talliaferro, Barron and Caruthers flying fields were located within a 14-mile radius of Fort Worth. In addition to the American aviators at the fields there were hundreds of members of the Royal Flying Corps of Canada.

Hard upon the heels of the establishment of the army camps came the news of the discovery of oil at Ranger, succeeded a few months later by a discovery of a new field at Burkburnett. These discoveries marked the beginning of the great West Texas fields which doubtless contain the largest oil reserves in the known world.

Meanwhile the cutting up of the great ranches of West Texas had begun.

Wheat fields in the Texas Panhandle produced so bountifully that with the high prices current in 1919 many farms were paid for out of the one crop. Cotton growing had been extended westward and in the South Plains the government tests had shown that cotton could be produced more cheaply than in any other section of the Cotton Belt. The sorghum grains, Kaffir corn, Milo maize and Feterita produced so bountifully throughout West Texas that the farmers were assured of a feed crop which made stock raising and feeding profitable.

All of these factors combined to bring a great movement of agricultural population into West Texas about 1920. Since that time the population of the area has increased at the rate of 100,000 a year. A recent survey of the population of thirty typical West Texas cities showed an average increase of 200 per cent since 1920.

West Texas is now producing new wealth to the value of more than three-quarters of a billion dollars a year. Petroleum and natural gasoline contribute

\$265,000,000; cotton and cotton seed \$175,000,000; livestock \$125,000,000, and grain \$100,000,000.

Fort Worth, the gateway to West Texas, its supply point and its market place, has naturally reflected this growth. Credited with a population of 106,482 in the 1920 census, a recent

senger station and terminal warehouses that will cost \$8,000,000. A good roads program in Tarrant County, of which Fort Worth is the county seat, involves the expenditure of \$10,000,000. Two dams on the West Fork of the Trinity River will cost \$6,500,000. The reservoirs created will give Fort Worth a water supply sufficient for 1,000,000 people and make possible the irrigation of 52,000 acres of land.

Probably the most constructive step taken by the City of Fort Worth during its recent history was the adoption of a new charter in 1925. Theretofore the city hall had been a rendezvous for politicians. But the charter provided for the Council Manager form of government. At the solicitation of voters, nine of the outstanding business and professional leaders of the city agreed to accept nominations as councilmen. They were elected and have since been returned at the two succeeding municipal elections. The only changes that have occurred have come through death or resignations.

The council chose a city manager of outstanding ability. Every department of the city government was reorganized. Public improvements that have cost many millions of dollars were undertaken and approved by the voters, who felt that they were getting the full worth of the money expended. Streets have been widened; underpasses provided; storm sewers built; water and sewer mains extended; white ways installed.

Absolute confidence in the integrity of the city government has resulted in the voters of Fort Worth standing behind every proposal for municipal improvements. A thoroughly modern metropolis, humming with industry and athrill with prosperity, has supplanted the "cow town" of thirty years ago.

Texas Hotel,

Headquarters for A. P. H. A. Meeting

survey indicates a present population of 202,316. It is a city of skyscrapers, pleasant parks, fine schools and colleges, and comfortable homes.

Some idea of its activities may be gained from the fact that in the city and county there is now under way a construction program involving \$60,000,000.

Bids have been called for by the Texas & Pacific Railway for a new pas-

ASSOCIATION NEWS

A. P. H. A. REPRESENTED AT LATIN-AMERICAN MEDICAL CONGRESS

UPON the invitation of officials of the Mexican Federal Health Department, Homer N. Calver, Executive Secretary of the American Public Health Association, and members of the Texas State Health Department staff attended sessions of the Latin-American Medical Congress held in Mexico City during the week of January 13. Delegates from the various states of Mexico and Central America, as well as South American republics, participated in the meeting. Also representatives of the American Public Health Association and the U. S. Public Health Service attended.

A joint conference was arranged for members of the Texas Health Department staff, the Federal Health Department of Mexico, the U. S. Public Health Service, and the American Public Health Association to discuss the importance of mutual coöperation in matters of sanitation along the Texas-Mexico border.

Preliminary plans were laid for a large delegation of Mexican health workers to attend the A. P. H. A. meeting at Fort Worth next October. Plans were considered also for delegates at that meeting to make a short visit to Mexico City.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Diphtheria Problem—Diphtheria, scarlet fever, measles, and whooping cough are primarily diseases of childhood although the first two mentioned are frequently met with at other ages. The diphtheria bacillus has been found in 12 per cent of new-born babies but in 60 per cent of such instances the mother was infected at the same time as the child.

Particular attention is drawn to mild or "missed" cases which determine in individuals an immunity which is considered to be natural but which is in reality due to an unobserved mild attack.

Diphtheria morbidity began to decline in most European countries around 1894 before the general use of antitoxin, although in several countries the incidence remained at a fairly constant level. After this decline the morbidity has remained almost stationary in the majority of countries. The fall in the amount of the disease since 1895 may have been due in part to the general improvement of living conditions among the poorer classes. Epidemics of diphtheria in Europe during the middle of the last century may, however, have produced a natural immunity in the population. It is a well known fact that a number of epidemic illnesses may confer immunity on a large section of a population resulting in the prevalence of milder forms of the disease. When antitoxin was discovered (1895-1896) the disease had only a slightly higher morbidity than is the case at the present time.

On the other hand, the mortality from diphtheria has diminished considerably—in Norway from 79.8 per 100,000 in-

habitants in 1894 to 25.2 in 1895 and 17.0 in 1896; in the Netherlands from 33.2 in 1894 to 20.7 in 1895 and 19.6 in 1896. Similar mortality drops occurred in Germany, Denmark, Scotland, France and Italy. In England prior to the introduction of antitoxin the mortality had been much lower than in some of these continental countries and the reduction since that date has not been so pronounced. In fact the English mortality during recent years (1925 to 1927) has been higher than that of the other countries.

A high proportion of cases with paralysis has been reported during the last three years. The case mortality has been high and has varied among different races. Fletcher examined 276 school children, of whom 172 were Malays and 104 Chinese, in the Federated Malay States. The Schick reaction was negative among the Chinese and Hindus in 76 per cent of cases, while among Malays the test proved negative in 91 per cent of cases. American workers have found a high per cent of natural immunes in the Philippines.

The relative absence of diphtheria in the tropics can be attributed to the large number of immune persons. Perhaps such immunity is due to widespread epidemics in past centuries which were not reported. Park and Zingher have shown that Italian children are more immune than American. This is attributed rather to difference of social state, as the Italian born children belong to the poorest classes of America.

The natural immunity which exists among tropical peoples may possibly be due to the same causes as produce immunity among the

poorer classes in the United States and in Europe. Such causes appear to be of a social rather than a racial order, because the great majority of natives of tropical countries belong to the poorer classes. The spread of epidemics of diphtheria among the peoples living under conditions of over-population and lack of sufficient material supplies has led to the production of an immunity which is now termed natural.

Active immunization against diphtheria is now practiced in three principal ways, (1) toxin-antitoxin, (2) anatoxin, and (3) vaccines. Immunization by vaccination, by mouth and by friction with an ointment containing bacteria and toxoid has been attempted. (The author describes results reported for each method.)

The value of active immunization against diphtheria, practiced according to recognized methods, is undoubted. The control of diphtheria mortality, which during the last few years has suffered a partial check, appears now to have taken a new form, and the time is perhaps not far off when lasting progress is assured.—General Review of the Diphtheria Problem in Recent Years, *Month. Epidem. Rep.*, League of Nations, June 15, 1929.

Cancer Studies—For the past 6 years Detroit has had a "cancer week" to teach the public early symptoms and the need of early diagnosis and treatment. During these special weeks, 7,767 individuals have presented themselves for examination. Four per cent have been found to have cancer, and an additional 12 per cent have had precancerous conditions requiring attention.

In 1927 the Detroit Department of Health established a Division of Cancer Control with an annual appropriation of \$16,000. The personnel included 3 part-time physicians, 2 public health nurses and 1 clerk. Starting with the death certificate an epidemiological study has been made of every cancer death from the onset of symptoms to the diagnosis, the record of treatment, and subsequent course after treatment. A Central Follow-up Registry has been established for living cases which are voluntarily reported by private physicians and hospitals. These follow-up histories are being made available to the profession through the county medical society.—Harry C. Saltzstein, Cancer Educational Activities, *City Health*, Detroit Health Dept., Nov.-Dec., 1929.

LABORATORY

C. C. YOUNG, D. P. H.

REPORT OF LIGHT TYPHOID OUTBREAK IN WHITTIER, CALIF., WITH SPECIAL REFERENCE TO THE LABORATORY FINDINGS

LEONARD HEDDICK

Murphy Memorial Hospital, Whittier, Calif.

IN the latter part of October, 1929, a light outbreak of typhoid fever occurred in Whittier, Calif. The first 3 cases were diagnosed and reported simultaneously to the Health Officer, Dr. F. G. Crandall, who immediately started an investigation. It was found that all of them consumed raw milk from the same dairy company, which obtained its raw milk from two dairies. Inquiry at the distributing plant revealed that these patients used milk from one of these. Dr. Crandall ordered all milk from this dairy to be pasteurized until further notice. The source of infection was found and preventive measures instituted in less than 24 hours.

At the suspected dairy there were no cases of illness, but one of the milkers had gone home sick October 5, and had not returned. He was traced to his brother's home in Artesia, a few miles away, and was found to be convalescing from a recent illness diagnosed by his family physician as "intestinal flu." Typhoid had not been suspected and no laboratory tests had been made. This man was about to start work in the dairy of his brother with whom he had stayed during his illness. A Widal showed complete agglutination in 1-320 dilution, partial at 1-640, para A and B negative. Eight stool specimens were negative.

Dr. Crandall could obtain no clue as to where this milker got his infection, but felt satisfied that he was the source of the outbreak. There were 7 cases, 6 described here, the 7th being a relative of the milker from a distant city who visited him during his illness and later came down with the disease. Five of the cases consumed milk from the dairy implicated, the 6th being a child living in the same house with the milker. Five were young children, 1 a boy of 17, and 1 a man of 30 years of age.

This milker left the dairy October 5, and the following cases cropped up about 14 days after he left—the approximate incubation period.

Case No. 1—Widal negative, feces negative. Widal repeated after 2 days negative. Blood culture positive in 24 hours. Blood culture again positive in 24 hours after 4 days.

Case No. 2—Widal 1-40, only. Blood culture taken at the same time positive after 3 days incubation.

Case No. 3—Widal negative. Blood culture taken same time positive.

Case No. 4—Feces negative. Widal 16 days later positive 1-320 dilution.

Case No. 5—Widal positive 1-320.

Case No. 6—Two feces examinations negative. Widal positive 1-160, partial 1-640.

Case No. 7—A 2-year old child in the home of ill milker. Widal negative. Blood culture positive in 18 hours for Gram-negative motile bacilli. Feces 9 days after positive blood culture negative; on 10th day positive. The organism from this specimen showed rapid

and high agglutinating properties, being completely agglutinated in 1-16,000 dilution, incubation 30 minutes. The milker's serum agglutinated this organism up to 1-160.

SUMMARY

The offending organism was recovered from the blood in 4 of the 6 cases tested, and once from the feces in 4 during active stage of the disease. Four of these were confirmed by blood culture. The

Widals in these were, 2 negative, and 2 positive in 1-40 dilution, only, there not having been sufficient time for the patients to develop specific agglutinins. The organisms from the blood were proved to be *B. typhosus* on sugars and by agglutination with anti-serums. The earliest positive blood culture was 6 days after onset of symptoms, emphasizing the value of such cultures in early typhoid bacteremia.

THE STOLTENBERG DIFFERENTIAL STAIN FOR DIPHTHERIA BACILLI

HELEN H. OWEN AND MARIE BAND

Division of Laboratories and Research, New York State Department of Health Branch Laboratory, New York, N. Y.

A DIFFERENTIAL stain for diphtheria bacilli, recommended by Stoltenberg,¹ has been compared with Loeffler's alkaline methylene blue stain and Albert's stain for polar bodies.

The results of the three procedures were first studied with pure cultures, the series including 25 cultures of *B. diphtheriae*, 10 of *B. hofmanni*, and 7 of *B. xerosis*. Forms with polar bodies predominated in the cultures stained with Stoltenberg's or Albert's stain, whereas the predominating forms stained by Loeffler's method were solid or banded. No difference was noted in the morphology of *B. hofmanni* when stained by the three methods; all were solid or banded forms and no granules were observed. The cultures of *B. xerosis* showed forms with polar bodies as well as banded and solid forms with all three stains.

One hundred nose and throat cultures received for routine examination were stained by the three methods and morphologically characteristic diphtheria

bacilli were found in 45 with all of the stains. It was noted that young cultures of *B. diphtheriae* (incubated at 37° C. for from 6 to 12 hours), which with Loeffler's stain appeared as solid or banded forms, showed polar bodies with Stoltenberg's stain. The same cultures incubated for 24 to 48 hours showed polar bodies when stained with Loeffler's alkaline methylene blue. The morphology of *B. hofmanni* remained unchanged throughout the long incubation period and these organisms were so faintly stained that *B. diphtheriae* could be easily differentiated.

The formula and procedure for Stoltenberg's stain are as follows:

Malachite green	0.250 gm.
Toluidin blue	0.050 gm.
Haematoxylin or logwood extract	0.010 gm.
Distilled water	100.0 c.c.
Acetic acid	3.0 c.c.
Ethyl alcohol	3.0 c.c.

Stain for 1 minute. Then wash the preparations with tap water and dry. The granules appear red and the body green.

The stain is not recommended as a substitute for Loeffler's alkaline methylene blue stain for routine use as it does not as satisfactorily differentiate *B. diphtheriae* from *B. xerosis*, and other non-pathogenic forms with polar staining. It is recommended as a valuable confirmatory stain, however, since it aids in the differentiation of *B. diphtheriae*

from *B. hofmanni*, especially in young cultures, and is a very short and simple procedure.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Tuberculosis in Early Childhood
—This survey included the total deaths from tuberculosis in England and Wales for 1927. The period especially studied was the first 5 years of life, and the amount of tuberculous disease in all its forms at this time was compared with similar succeeding periods. The number of deaths, about 3,000 in the first period, birth to 5 years, exceeded that in the later period of childhood and puberty. In adolescence and throughout the prime of life, the figures were about or exceeded the 4,000 mark. The first phase of tuberculosis is therefore, as regards fatal disease, easily the most important of the whole period of childhood.

The relative prevalence of clinical types of tuberculosis was also studied, through the medium of the tuberculosis deaths in England and Wales for 1927. Only 3 types were chosen, meningeal, respiratory and abdominal. These do not constitute the whole of tuberculosis at the early period in childhood, but form the greatest and most important part of it. Meningitis easily took first place in the number of deaths for the first 5 years; and the total for this period was far greater than for any other period. Abdominal tuberculosis

also caused far more deaths at this period than at any later period. The number of deaths from pulmonary tuberculosis practically equalled that from abdominal tuberculosis in the first period. In the first 5 years of life, in England and Wales, the deaths from tuberculous meningitis were 3 times greater than those from pulmonary and from abdominal tuberculosis.

A study of 254 cases of tuberculosis admitted to the Royal Edinburgh Hospital for Sick Children during the past 8 years showed that 181 cases occurred under 5 years of age. Of the 91 cases of meningeal tuberculosis, 73 occurred under 5 years. Death resulted in all cases. Post-mortem examination was made in 51 cases and the primary lesion revealed in all but 2. In this group of 181, there were 27 cases of pulmonary tuberculosis with 19 deaths. Pulmonary tuberculosis is very difficult to diagnose in the period of infancy because it assumes a variety of forms. In the first 5 years, there were 81 cases of abdominal tuberculosis with 43 deaths. Throughout northern England and Scotland; abdominal tuberculosis is a grave peril, being caused by infected milk in most cases.—*Brit. M. J.*, 2: 655-658 (Oct. 12), 1929.

VITAL STATISTICS FOR 1929

Metropolitan Life Insurance Co.—Continued progress of the American and Canadian public health movement is shown in the mortality records for nearly 19,000,000 industrial policy holders of the Metropolitan Life Insurance Company during 1929. There occurred 8.7 deaths per 1,000 lives, a figure identical with that for 1928. The outstanding public health fact of 1929 was the reduction of the tuberculosis death rate to a new minimum. The death rate now stands at 85.6 per 100,000. The previous low point was 90.6, recorded in 1928. The outlook at the present time is that the downward swing of the death rate will continue, and 10 years from now the tuberculosis death rate among these wage earners will be well on its way toward 40 deaths per 100,000.

Another new low point was reached in 1929, in the mortality rate for typhoid fever. The death rate (2.3 per 100,000) marks a decline since 1911 of 89.9 per cent.

The death rate for the four principal communicable diseases of childhood (measles, scarlet fever, whooping cough and diphtheria) in 1929 was only 16.3 per 100,000, or 14.2 per cent below the previous minimum of 19.0, recorded in 1928. The outstanding item in this group is diphtheria, with a 1929 death rate of only 8.5 per 100,000, as compared with 9.5 (the previous minimum) in 1928. Scarlet fever duplicated its minimum death rate of 1928 (2.6 per 100,000). There was a small rise in the mortality from whooping cough.

The death rate for diarrhea and enteritis reflects closely the advancing standards of domestic and civic hygiene. The mortality rate for this cause has now declined to 7.8 per 100,000—or almost to one-quarter of the figure registered 18 years ago.

One of the most encouraging developments in 1929 was the recording of a new minimum death rate for diseases and conditions incidental to pregnancy and childbirth. The rate, 13.5 per 100,000, was lower by 4.9 per cent than the previous minimum of 14.2 in 1928.

The suicide death rate of these insured wage earners was 8.5 per 100,000 in 1929, which is identical with that for 1928, but higher than for any other year since 1917. The homicide death rate declined slightly.

For certain diseases and conditions the 1929 mortality record was somewhat unfavorable. The early months of the year experienced the heavier part of the wave of influenza and pneumonia which began in November of the preceding year. The heart disease death rate, in 1929, was 146.1 per 100,000 as compared with 144.4, the previous maximum, in 1928. The rise in the rate for cardiac conditions in 1929 is chargeable almost entirely to the effects of the influenza epidemic, which hastened the deaths of many thousands of persons suffering with chronic diseases.

The cancer death rate continued its slow, persistent increase to a new high point. The 1929 mortality rate was 77.3 deaths per 100,000 policy holders as compared with 77.0 in 1928. The most recent investigation into cancer mortality by the Metropolitan Life Insurance Company has developed certain important aspects of the upward trend of the death rate, and has shown that the gravity of the cancer problem is much greater than it was only 5 years ago.

The previous maximum death rate for diabetes was 17.9 in 1928, and the rise in 1929 amounted to 2 per cent. The diabetes mortality rate has now been increasing continuously for 5 years.

The mortality rate for accidents rose

slightly in 1929. This was due almost entirely to the alarming increase in automobile fatalities, although there were also more deaths than in the preceding year from falls and machinery accidents. The 1929 death rate for automobile accidents was 20.9 per 100,000, a rise of 12 per cent in a single year.

Acute and chronic alcoholism caused 641 deaths of policy holders during 1929, with a death rate of 3.4 per 100,000. This marks a slight increase over the record of 1928 when there were 599 deaths and a death rate of 3.3 per 100,000. Deaths from cirrhosis of the liver, which are largely of alcoholic origin, number 1,208 in 1929, as compared with 1,217 in 1928; the death rate declined to 6.5 per 100,000, from 6.7, in 1928.

The latest available mortality figures for the general population of the United States relate to the year 1928. Between 1911 and 1928 the death rate for the general population declined only 11 per cent, as compared with a drop of 31 per cent among Metropolitan industrial policy holders. In 1928, the crude mortality rate of insured wage earners was lower than that of the general population (of comparable ages) by 3.2 per cent.

For the communicable diseases of childhood, the corresponding figures are 68 per cent for insured wage earners and 62 per cent for the general population. The greater improvement which has obtained since 1911 in the death rate among Metropolitan industrial policy holders, as compared with the general population, has come largely from the company's activities in the fields of social service and public health among the many millions of insured people.—New Low Records for Mortality in 1929, *Stat. Bull.*, 11: 1-10 (Jan.), 1930.

Milwaukee, Wis.—Health conditions in the city of Milwaukee were on the

whole very satisfactory, in spite of the fact of the influenza epidemic and the most severe measles epidemic in the history of the Health Department. The general death rate for the year was 10.5 compared to 10.9 for the previous year, and was somewhat lower than the average for the last 5 years. Infant mortality was 72 per 1,000 live births compared with 70 for 1928. The principal cause of deaths in babies over 30 days old was pneumonia, 162 babies dying from this cause during 1929. There were 886 infant deaths under 1 year, 12,232 live births and 327 stillbirths, compared to 846 infant deaths under 1 year, 12,120 live births and 375 stillbirths in 1928. There were 13,198 cases of measles with 25 deaths reported during the year. Whooping cough showed the next greatest increase with 3,806 cases and 40 deaths. All other contagious diseases showed decreases. Tuberculosis with 259 deaths showed an encouraging decrease over 1928 with 292 deaths. Heart disease and cancer showed the usual increase; there were 1,087 deaths from heart disease compared to 997 the preceding year, and 591 deaths from cancer compared to 578 the year before. There were 108 automobile deaths compared to 124 for last year. Deaths from alcoholism increased from 21 in 1928 to 27 in 1929. There were 5 deaths due to carbon monoxide poisoning.—*Milwaukee Month. Health Bull.*, 19: 2-5 (Feb.), 1930.

New Haven, Conn.—The estimated population of New Haven for 1929 was 190,847. During the year, there were 2,181 deaths, giving a death rate of 11.4. The most striking feature was the marked reduction in the infant mortality from 53 in 1928 to 42.4 in 1929. The birth rate dropped again to a new low point of 14.6. Among the 10 leading causes of death, heart disease still held the lead; tuberculosis was in 5th

place, and deaths from auto accidents ranked 8th. The tuberculosis death rate of 49.25 showed a substantial drop from the previous year. There were 6 resident cases of smallpox during the year. The substantial control of diphtheria was striking. There was 1 less case in 1929 than in 1928, and there were only 2 resident deaths as against 6 for the previous year.—*New Haven Month. Health Bull.*, 57: 2-7 (Jan.), 1930.

Victoria, British Columbia—The population of Victoria according to the 1928 census was 43,750. The death rate for 1929 was 13.1 per 1,000 population as against 13.9 for the preceding year. The birth rate was 18.1 for 1929 and 20.1 for 1928. Infant mortality decreased from 42.2 per 1,000 live births in 1928 to 40.3 in 1929. The latter was 37.9 for whites and 72.7 for Asiatics. With the exception of a somewhat greater summer incidence of measles and mumps, 1929 was light in communicable diseases. There were 57 cases of pulmonary tuberculosis with 25 deaths.—*Annual Report for 1929*.

Lincoln, Neb.—A study of the mortality records for 1929 shows an increase of 43 deaths over the previous year, 29 of which are accounted for by an increase of organic heart disease. Deaths from nephritis show a decrease of about 14 per cent. Mortality from malignant disease is about on a level with preceding years. There has been no further decrease in deaths from puerperal infections. The increased mortality has occurred chiefly in the age group 5 to 25, which shows an increase of 55 per cent, and the old age group, 65 and over. There were 25 less births in 1929 than in 1928 and 92 less than in 1927; a decrease of 6.5 per cent in 3 years. There was a much larger proportionate decrease in stillbirths; 34 per cent over the same period.—*Annual Health Report*.

Buffalo, N. Y.—Buffalo had an estimated population of 555,800 for 1929. The annual death rate was 13.8 per 1,000 compared with 13.4 in 1928. There were 11,685 births corresponding to a rate of 21.0 per 1,000 against 21.7 in 1928. Infant mortality decreased from 74.0 per 1,000 live births in 1928 to 66.1 in 1929. There were increases in the number of deaths from organic diseases of the heart from 1,335 in 1928 to 1,749 in 1929; cancer, 666 to 678; pneumonia, 419 to 501; automobile fatalities, 150 to 196; diabetes, 97 to 119; and suicides, 61 to 72. Noteworthy among decreases were pulmonary tuberculosis, 404 to 390 in 1929; other forms of tuberculosis, 90 to 75, and nephritis, 254 to 251. The number of cases of measles declined from 6,502 in 1928 to 975 in 1929.—*Buffalo Month. San. Bull.*, Dec., 1929.

Boston, Mass.—The Boston Department of Health announces that the estimated birth rate for 1929 was 22.7 per 1,000 population, as against 23.5 in 1928. The death rate from all causes was 14.5, the same as in 1928. There was an infant mortality rate of 68 per 1,000 live births, as against 77 in 1928. Among the leading causes of death were 2,230 from heart disease, 1,245 from cancer, 1,411 from pneumonia, and 574 from pulmonary tuberculosis.—*Boston Month. Health Bull.*, Jan., 1930.

Maryland—During 1929 the birth rate in Maryland was 18.5 per 1,000 population. This is the lowest recorded since 1912. The death rate from all causes for the year was 13.4. There was an infant mortality rate of 79 per 1,000 live births. The rate in Baltimore was 73 and in the counties it was 85. The leading causes of deaths were heart disease with a rate of 233.2 per 100,000 population; influenza and pneumonia with a rate of 178.2; nephritis 148.4; cancer and other malignant tumors 108.3; tuberculosis, all

forms, 104.2; and cerebral hemorrhage 100.3.—*Maryland Month. Bull.*, Feb., 1930.

Newark, N. J.—The Health Department of Newark has announced in a preliminary statement that there have been fewer infant deaths, and a reduced mortality from cancer, Bright's disease and nephritis, and puerperal fever in 1929 over the previous year. Both the crude death rate, 11.6, and the adjusted rate, 10.9, per 1,000 were the same as in 1928. The infant mortality rate of 60 per 1,000 live births was one of the lowest ever recorded for the city. Deaths from Bright's disease numbered 254, a figure 44 less than the preceding year. The 471 cancer deaths were 20 fewer than in 1928. Puerperal fever caused 16 less deaths, reducing the rate from 13.3 to 9.8 per 100,000. Deaths from heart disease numbered 1,057, or 55 less than in 1928. The death rate from organic heart disease, 220.2 per 100,000 population, was by far the highest of any rate for special causes. Increases in deaths from apoplexy, influenza, tuberculosis, accidents and suicide were noted. Reported cases of communicable diseases decreased 4,036 during the year to a total of 17,329. Fewer cases of measles accounted for most of this reduction.—*New Jersey Pub. Health News*, 15: 57 (Feb. 14), 1930.

Connecticut—The accumulated birth rate for 11 months showed a very decided drop from 17.5 in 1928 to 15.2 in

1929. The death rate of 10.9 is the same as it was in 1928, which is encouraging because of the influenza outbreak early in the year. For the 11 months of 1929, decided increases were shown for influenza, cancer, diseases of the heart, and diarrhea under 2 years. Noteworthy among decreases were whooping cough, diphtheria, all forms of tuberculosis, diabetes, nephritis, and puerperal diseases. It now seems as if 1929 will show the lowest death rate from diphtheria in the history of Connecticut vital statistics and it is possible that the death rate from tuberculosis will reach a record low.—*Conn. Month. Health Bull.*, Jan., 1930.

Infant Mortality in Bombay—The number of births registered in Bombay in 1928 exceeded that of the previous year by over 2,000; it was more than 3,000 above the annual mean number of births registered in the 10 years, 1918–1927. Calculated on the estimated population for 1928, the birth rate was equivalent to 18.5 per 1,000; the number of live births recorded was the highest since 1866.

The death rate among infants under 1 year was 311 per 1,000 registered births, a figure which contrasts sharply with the calculated infant death rate of 176 per 1,000 for the whole of British India, but it is an improvement on 316, the 1927 rate, and on 474, the annual average in the decennium 1918–1927.—*Brit. M. J.*, 2: 1082 (Dec. 7), 1929.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Sewage Disposal. The Activated Sludge Process in Operation. Standards of Purity—The activated sludge process is far more likely to supplement than to supersede the older methods. Common mistakes made in connection with its use and the wisdom of not dispensing with filters are considered. It has been found that the purification effected by the activated sludge process is at first very rapid, but it soon slows down, e.g., 60 per cent of the impurities of the Birmingham sewage are removed in the first hour, but it takes 5 hours to remove another 30 per cent.

The quantity of sewage purified by each cu. yd. of filtering material is more than doubled when the sewage has been treated by the activated sludge process instead of merely being passed through a sedimentation tank. Thus, owing to the rapid increase in the population of the drainage district under the Tame and Rea Drainage Board, aeration or flocculation tanks are used between the sedimentation tanks and filters to obviate the necessity of laying down an additional acre of filters each year.

Opinions differ as to the purification standards and nature of tests to be used. Lord Iddesleigh's Commission recommended a common sense standard to be applied in ordinary cases, the dilution afforded by the stream being considered before the application of the standard. With a dilution exceeding 500 volumes, all tests might be dispensed with. No biological standard has been advocated, those proposed or in force relating solely to the chemical qualities of the effluent. The effluent from a sewage works must

therefore be regarded as potentially dangerous.—A. J. Martin, *Surveyor*, 76: 366, 1929. (From Papers of Water Pollution Research Board, England.)

Artificial Means of Influencing the Formation of Ground Water in Flat Country—The author considers that it is possible to increase the amount of ground water in a flat country by artificial means at the expense of surface flow-off and evaporation. The seepage of rain through the fine-pored surface layer causes an increase of air pressure in the lower larger-pored stratum, which may increase above the atmospheric pressure and force water to the surface. The author carried out investigations of the growth of this air pressure and of its effect on seepage and the increase of ground water. The pressure in the coarse layer was observed by inserting a pipe carrying a manometer. A method of estimating the amount and increase of ground water is described. It was found that the underground river which flows through Munich only receives some 10 per cent of the precipitation of the district through which it flows. The author suggests that methods for increasing the amount of ground water are: to increase the air drainage in the coarse-pored stratum above the water surface, and to increase the flow of water and the depth of channel. He describes an arrangement for air drainage either by vertical slotted pipes reaching almost through the coarse layer or, if the fine upper layer is thin, by horizontal slotted pipes with vertical pipes to the surface at intervals. This arrangement should be combined with

water intakes (seepage galleries, wells, etc.), and, where necessary for agricultural purposes, with a pressure pipe so that water can be forced to the surface.—Mezger, *Gas- und Wasserfach*, 72: 948, 1929. (From Papers of Water Pollution Research Board, England.)

Water Supply of Hither Pomerania—With its scattered population, Hither Pomerania is almost entirely supplied by single wells. The results of 50 bacteriological and 360 chemical investigations of well waters are summarized; of these 90 per cent were chemically and bacteriologically to be condemned. Of 33 samples of water from dairies, 21 were bacteriologically impure and only 5 were chemically acceptable. Of 16 school well waters, 14 were to be condemned. Of 50 bacteriological tests, 15 were usable, 3 usable under certain conditions, and 32 unusable.

The true underground water in Pomerania lies some 40 meters deep between glacial deposits. Most wells only reach a "surface" underground water, above the latest glacial deposit, which is not cut off from pollution by sewage, etc. Also the building of wells is generally bad. Water supplies for drinking purposes should be taken from the second ground water zone or from one deeper still.—Lensden, F. P., *Z. f. Medizinal-beamte*, 1929, 42, 40; *Gas- u. Wasserfach*, 1929, 72, 960. (From Papers of Water Pollution Research Board, England.)

Sewage Disposal. Johannesburg's New Sludge Digester—This account is taken from a paper contributed to the South African Institution of Engineers by E. J. Hamlin. The new type of digester unit adopted by the Johannesburg Council consists of a flat-bottomed cylindrical tank with steel superstructure carrying the mechanism and driving unit

and supporting the gas collecting tank cover. A central vertical revolving shaft carries horizontal radial arms near the surface which distribute the feed and break up the scum and, at the lower end, radial arms, to stir the sludge and move it toward the discharge cone, and a scraper in the discharge cone. Excess liquor runs off through an opening in the tank wall. The advantages of mechanical operation are said to be reduction in tank volume, even discharge of gas, and assurance of a completely digested sludge. The amount of gas is calculated at $\frac{1}{2}$ – $\frac{3}{4}$ cu. ft. per head per day.—*South African Eng.*, 40: 193, 1929. (From Papers of Water Pollution Research Board, England.)

The Fertilizing Value of Sewage Sludge—The fertilizing value of sewage sludge depends upon the percentage of available phosphoric acid, total nitrogen, and water-soluble potash. As fertilizers, sewage sludge appears to be divided into two distinct groups: one, sludge from Imhoff tanks and similar processes, and the other that from activated sludge processes. In the Imhoff tanks, where fermentation in the absence of air takes place, the sludge goes through an extensive decomposition, leaving only the more resistant portions. The nitrogen in these more resistant portions, to be taken up by plants, must be decomposed by soil bacteria. These facts indicate why this type of sludge has not proved to be such a good fertilizer as that from the activated sludge process. Sludge from an activated plant is easily decomposed by soil bacteria and has a good availability. Of course, all activated sludge is not of equal value, because some may contain nitrogenous compounds of lower activity, which will decrease the availability of nitrogen.

Comparative analyses of two types of sludge, dried to about 4–8 per cent water, follow:

	Imhoff per cent	Activated per cent
Phosphoric acid	0.47-2.48	2.41-2.68
Nitrogen	0.88-2.99	3.69-5.54
Potash	0.2-1.44	————

Based on these figures, the retail fertilizer value of the Imhoff sludge would be about \$6.55 and that of the activated about \$22.65.—G. S. Fraps, *Proc. Eleventh Texas Water Works Short School*, Jan., 1929, pp. 150-152.

A Study of Lead Poisoning in a Storage Battery Plant—This study was a sanitary survey made of a small plant, of 56 employees, devoted to the manufacture of storage batteries. Air analyses were made of the various rooms where the employees worked. In only one of the six working rooms was the air free from lead. The amount of lead found was from 0.009 mg. per cu. ft. of air to 0.0453 mg.

Workers from each of the above rooms were studied and the clinical findings were recorded for each group. These data indicate that the greatest exposure existed in the assembly room, where 7 of 10 men examined showed positive lead poisoning. This high rate is due to the finely divided state of lead encountered by the working men.

The study revealed that workers exposed to 0.009 mg. of lead per cu. ft. for a period of 1½ years are not affected with chronic lead poisoning. However, if the duration of exposure is continued for 2½ years, chronic lead poisoning develops. Necessary changes in mechanical equipment and operation are suggested in order to minimize the lead dust hazard.—Leonard Greenburg, A. A. Schaye and H. Shlionspy, *Pub. Health Rep.*, 44, 28: 1666-1698 (July 12), 1929. Abstr. M. S. Foreman.

Mastitis—Raw Milk Combination Causes Another Epidemic—Following an outbreak of approximately 75

cases of mastitis in Savannah, Wayne County, N. Y., which has a population of about 600, an investigation revealed all cases investigated had used a Grade A raw milk from one dairy. Further investigation showed that one cow in the herd had received an udder injury about March 2, that a veterinarian reported no inflammation on March 6, that mastitis was discovered on March 13, and the milk not excluded until after that date.

The department's position is stated as follows: (1) that acute mastitis is a serious health menace; (2) dependency on the farmer for discovery and action is unsatisfactory; (3) monthly veterinary inspection or weekly bacterial examination of the milk or both provide a safeguard although not an entire one; (4) certain safeguard is effective pasteurization.—Anon., *Health News*, New York State Dept. of Health, 6, 13: 49 (April 1), 1929. Abstr. F. O. A. Almquist.

Pre-Determining the Extent of a Sewage Field in Sea Water—A description of a method of pre-determining the probable area and extent of a sewage field in sea water, given the quantity of sewage flow and the direction and depth of discharge. The behavior of fresh water jets in sea water was first studied, and experiments were afterward instituted in a basin of some 2 acres in extent in Los Angeles Harbor.

Fresh water colored with eosin Y was discharged into the basin from a tank on a raft; the underwater process was watched by reflection and the dilution measured by comparison with measured dilutions of the tank water. Experiments were made with vertical jets (downward and upward), horizontal jets, jets discharging upwards at 45°, and multiple jets.

Equations are given for determining the dilution of a discharge with a probable error of 4-5 per cent. Corroborations

tion and correction of the method from observations in practice are discussed and examples of its application given.—A. M. Rawes and H. K. Palmer, *Proc. Am. Soc. Civil Eng.*, 55: 1167, 1925 and 2221, 1929.

Technical Aspects of the Prevention of Pollution of Rivers by Domestic Sewage and Trade Wastes—Questions relating to the pollution of rivers, such as standards for effluents, methods of purifying domestic sewage, pollution by storm overflows, the activated sludge process, sludge disposal, trade wastes, laws governing the admission of trade wastes into sewers, the problem of spent gas liquor, financial difficulties militating against sewage treatment, and disposal by dilution, are discussed in outline. The author sums up as follows:

Any domestic sewage, and the large majority of trade wastes, can be purified—at a cost. The engineer is ready to do his part; the river, if given a chance, will complete the work. The chief hindrances to the purification of rivers are not technical, but financial, legislative and administrative.

—Arthur J. Martin, *J. Roy. San. Inst.*, 49, 12: 677–686 (June), 1929. Abstr. A. W. Fuchs.

Sewage Plants and Mosquito Propagation—Investigation of 42 sewage treatment plants in Bergen County, N. J., showed that 18 were directly responsible for mosquito breeding. Four examples are given: (1) An Imhoff tank sprinkling filter effluent discharging to a creek bottom, causing overflow to seven acres of meadow land, and heavy growth of mosquitoes; (2) sewage from a town one and one-half miles above a small lake of 10 to 15 acres caused mosquito breeding, requiring drainage of lake for control; (3) sewage plant effluent pooled on open meadow of three or four acres caused heavy breeding; (4) sewage plant efflu-

ent runs 1,500 feet through pipe to tide water. At high tide effluent backs up and overflows, spreading 1,000 feet on each side of pipe in cattails on low land, causing growth of mosquitoes.—John P. Peterson, *Munic. News & Water Works*, 76, 7: 288 (July), 1929. Abstr. E. A. Reinke.

On the Nature and Removal of Effluents from the Brown Coal Industry—Briquet water requires only mechanical purification though precipitation is necessary when the water is very acid. Effluents from the briquetting furnace contain nitrogen, sulphur, and carbon-oxygen compounds. The condensate contains carbon compounds in the form of alcohols, aldehydes, ketones, acetic acid and phenols. In contrast to hard coal, there are mainly present cresol or creosote, hydroquinone, resorcin, pyrogallol, and phloroglucin, all of which, in the presence of water and alkali, form resins. These effluents are very harmful to animal and plant life. The modern carbonization ovens give rise to large quantities of effluent containing 0.1–0.2 per cent of nitrogen (90 per cent as ammonia) and 0.4–0.8 per cent of phenol. Rotary generators give a very concentrated and harmful effluent. In the production of crude gas from briquets, an effluent is produced like that from the carbonization oven. Evaporation of this effluent is only economically possible when waste heat can be used. De-phenolizing is only economically possible when the content is over 2 gm. per litre. Biological processes are expensive and the lack of domestic sewage in brown coal districts makes them impossible. Only physical-chemical processes remain. Filtration through ashes has given good results and phenol can be recovered by absorption by activated carbon.—H. Stoeff, *Z. angew. Chem.*, 42, 29: 783, 1929. (Papers of Water Pollution Research Board, England.)

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Lead Poisoning—The compounds of lead alone are poisonous, the handling of metallic lead and its compounds being harmless in the absence of dust. Two mg., i.e., 1/32 gr., absorbed daily will in time undermine the constitution and set up chronic lead poisoning with changes in the kidneys and arteries which will shorten life.

Industrial lead poisoning is entirely due to inhalation of leady dust or fume and not at all to handling. Absorption takes place far more generally through the lungs than through the alimentary canal. In its prevention, influences brought to bear external to the workman over which he can exercise no control, bring about the most brilliant successes in handling lead poisoning. Failure and disappointment result where this principle has not been applied as in lead smelting works, electrical accumulator factories and in house painting.

The essential thing in the decrease of poisoning in white lead works has been the discovery that the carbonate of lead has much greater affinity for oil than for water. In pottery manufacture, the drop has been due to the decreased solubility of the form of lead glaze used. The fall in the manufacture of paints and colors has been due mainly to locally applied exhaust ventilation. In the other industries mentioned above, failure to prevent lead poisoning is due to the fact that no method of cutting out the personal element has been universally applicable. Yet in one accumulator factory employing about 1,000 persons in contact with lead and in which there were 11 cases of poisoning in 1926 and 18 in 1927, after the engagement of a whole-time works sur-

geon to study the men in the work there were no cases reported in 1928 and none up to July, 1929.

The fall in coach painting is due to the absence of white lead in the paint, largely owing to the enormous development of spray painting of motor cars, etc., in which employers are too sensible and too frightened to use lead compounds as an ingredient of cellulose sprays. The substitution of zinc base and titanium oxide in the internal painting of buildings has resulted in a decrease of lead poisoning among house painters. In France one is impressed with the much more beautiful effects and brighter colors of their buildings with none of the dirty drab color characteristic of white lead after a short exposure to the atmosphere.

The reason that the proportion of deaths to cases is relatively so much higher in the pottery industry and house painting than in others is not that they are so much more dangerous, but because workers engage in them for longer periods and become the victims of chronic lead poisoning with its sequela of saturnism, such as Bright's disease or cerebral apoplexy, both of which are compensable under the Workmen's Compensation Law.

Figures show that females are attacked by lead poisoning about twice as frequently as males. They suffer more from headache and brain symptoms, while there is no doubt as to the baleful influence of lead on uterine function, and because of the last, employment in lead should be barred where there is interference with the function of maternity.

Most cases of lead colic occur within

the first two years of employment, while paralysis (wrist drop) is always a late symptom and is more frequent in men because their duration of employment in lead exposure is much the longer. A Recommendation of the General Conference of the International Labor Organization held in Washington, in 1919, urged that

In view of the dangers involved to the function of maternity, and to the physical development of women, and young persons under the age of 18 years, they should be excluded from employment in the following processes.

These are, in brief, concerned with the reduction of zinc or lead ores, the desilvering of lead, the melting of lead or old zinc, the manufacture of solder or alloys containing more than 10 per cent of lead, the manufacture of various lead compounds (named) which are used in paints and glazes, and work upon electric accumulators.

It is further recommended: The employment of women and young persons under the age of 18 years in processes involving the use of lead compounds be permitted only subject to the following conditions

(named), in regard to working conditions, notification, compensation, medical examination, protective clothing, eating places, etc. These points have been embodied in the "Women and Young Persons Act, 1920."

At the present time in this country (England and Wales) lead poisoning cases are twice as severe and the amount of chronic poisoning four times as great among house painters as among factory workers, yet there is little evidence that male lead workers are less likely to beget children although there are so many variables to consider in a question of this sort that a definite conclusion is difficult.

An analysis of 10,923 cases of lead poisoning in the past 30 years has brought out certain essential facts such as the reduction in severity and in the number of chronic cases, and conse-

quential increase in the moderate and slight attacks. Reduction in severe cerebral symptoms is very important since these must be regarded as due to lead dust or fume. It was the cases of convulsions and blindness in quite young girls 30 years ago which agitated the public mind. Epilepsy, mental defect, and optic neuritis as symptoms of lead poisoning have decreased, in some cases remarkably.

Among 6,499 cases of lead poisoning were 680 of paralysis and 603 of muscular weakness. The right forearm is shown to be considerably more affected than the left in both paralysis and weakness. The testing of the strength of grasp and of the fingers and wrists is "the most useful single test there is for detecting chronic lead absorption rapidly." Another most remarkable feature is the wrist drop consequent upon the selective toxic action of lead on the musculo-spiral nerve.

An accompanying chart shows that the chief paralyses and weaknesses involve, in descending order: (1) both forearms, (2) the right forearm in respect to paralysis but the arms and legs together in respect to weakness, (3) the left forearm alone in both conditions, and (4) the arms, legs, fingers, etc. (The author next pokes fun at "the great ethyl petrol stunt" which used the time and attention of 11 experts from April 2 to July 16, 1928, in coming to the unanimous conclusion "that there were no reasons for prohibiting the use of ethyl petrol." Not a single case of lead poisoning from this substance has been reported in the country.

Lead poisoning can only be prevented; it cannot be cured. Symptoms can be treated and relieved. While saying this I am not unmindful of the undoubted progress that has been made recently of how lead acts when absorbed into the system by Drs. Aub, Fairhall, Minot and Reznikoff working in the Harvard School of Public Health.

Their experiments proved that lead en-

ters the organism most rapidly by the respiratory tract; hence inhalation of lead or its compounds in the finely divided state is to be most guarded against.

Analysis of reports on 10,929 cases of lead poisoning shows in general the following: *severe* cases have included paralysis, encephalopathic conditions—convulsions and mental affections, and grave undermining of the constitution associated with Bright's disease and arteriosclerosis; *moderate* cases have included: a combination of colic with anemic, profound anemia, partial paralysis, and cases in which there is constitutional debility; while *slight* cases have included colic, constipation and rheumatic pains, anemia, and either of the above with muscular weakness.

Accompanying tables, as already stated, show a noticeable decline in severity of cases in the last 5-year period as compared with the first 2; brain symptoms are distinctly fewer; cases of paralysis fewer than they used to be (which general statement also applies to "weakness of the arms").

The tables show also the percentage by sex of such main symptoms as: "gastric, anemia, headache, paretic, encephalopathy, rheumatic, and other," divided into four 5-year periods, 1900–1924 inclusive.—Sir Thomas Morison Legge, late H. M. Senior Medical Inspector of Factories (England and Wales), *J. Roy. Soc. Arts*, LXXVII, 4007: 1023–1039 (Sept. 6), 1929.

Occupational Diseases in 1929 Show Lead Poisoning Led in Fatalities—This is a preliminary summary of 1,381 occupational disease claims filed with the Industrial Commission of Ohio for the year 1929. These claims, of course, have not all been allowed and some of them have been proved not to be occupational diseases. In the total were 78 claims for

tenosynovitis which was not on the list of compensable diseases during 1928. Also, 102 claims were for afflictions not on the compensable schedule, leaving 1,279 to be considered by the commission for payments.

Of 37 death claims, 9 more than for the year 1928, 10 were for non-compensable diseases and the remaining were for the following: dermatitis 3, lead poisoning 19, benzol or derivatives 2, anilin poisoning 1, volatile petroleum products such as benzine or naphtha 2.

There was a total of 911 claims for occupational skin diseases which, exclusive of the 3 death claims, had an average period disability of 11 days each. There was a total of 189 claims for lead poisoning for which, deducting the 19 death claims, the average number of days lost per claim was 33. There were also 61 claims for compressed air illness.

In the group of 102 non-compensable claims there were 30 cases of tuberculosis, 13 asthma, 21 bronchitis, 6 poisonings, 11 infections or contagions, 10 inflammatory conditions, 5 various forms of neuritis, and 4 arthritis, with 2 not classified. [A considerable number of the claims for lung conditions were found to be due to silicosis and other forms of pneumokoniosis according to the records of the same cases which were investigated by the State Department of Health.—E. R. H.]—Unsigned, Ohio Industrial Commission Monitor, 3, 2: 303 (Feb.), 1930.

New Rule Applying to Minors Employed in Spray Coating Operations—The following rule was adopted by the Industrial Board of the State of Pennsylvania at its meeting on October 16, 1929:

No person under 18 years of age shall be required or permitted to spray coat objects with any substances containing lead, benzol, or ground siliceous material.—

Labor & Industry, Pa. Dept. of Lab. & Ind., Harrisburg, XVI, 11: 5 (Nov.), 1929.

Laboratory Facilities to Assist Industry—The facilities of the laboratory and technical service of the Connecticut State Department of Health are offered to industries of that state for the determination of gases, dust, fumes, and toxic materials; air velocity, temperatures, humidity, ventilation, or any conditions or processes affecting the health of employees.

A number of studies have already been made for industries doing sand blasting, such as the determination of the efficiency of the protective devices provided and practical suggestions to decrease the dust hazard to the workers exposed. Studies of causes and methods of prevention of dermatitis have been made as well as studies of other environmental working conditions.—Division of Industrial Hygiene, *Connecticut Health Bull.*, 44, 1: 20 (Jan.), 1930.

Compensable Occupational Disease Institute—This course was planned to meet the need for definite information about occupational diseases included in the New Jersey Compensation Law. It was also conducted for industrial managers and physicians. The subjects were arranged for Tuesday evening each week for 5 weeks to consist of lectures with illustrations, followed by round table discussions.

The first lecture considered Industrial Poisons, Dr. Harrison S. Martland introducing the subject and discussing the effects, and the Hon. John Roach discussing the Act relating to Industrial Diseases.

The second week included a lecture on Lead Poisoning by Dr. G. H. Gehrmann, of the E. I. duPont de Nemours & Company and by Dr. A. J. Lanza, Assistant Medical Director of the Metropolitan Life Insurance Company, and a

lecture on Carbon Monoxide Poisoning by Dr. May R. Mayer of the New York Department of Labor.

The third week's lecture considered Benzol Poisoning, presented by Dr. Leonard Greenburg of Yale University and Dr. H. F. Smyth of the University of Pennsylvania.

The fourth week considered Anthrax by Dr. Elizabeth B. Bricker of the Pennsylvania Department of Labor and Industry, and Chrome Poisoning by Dr. J. J. Bloomfield of the U. S. Public Health Service.

The fifth week comprised a lecture on Mercury Poisoning by Dr. Henry H. Kessler, Director of the New Jersey Occupational Disease Clinic, and a lecture on Wood Alcohol by Dr. R. H. Price of the E. I. duPont de Nemours & Company.—Newark Safety Council, Department of Labor, Occupational Disease Clinic, and the Essex County Medical Society (New Jersey), Feb. 11–Mar. 11, 1930.

Small Arms Ammunition—General information concerning the manufacture of cartridges and shells for rifles, shotguns, and similar small arms is discussed in this bulletin, including a brief review of the personnel and regulations in one of the government arsenals, as well as in two large private industries. There is also a classification of some 20 "Jobs" or industrial processes in the manufacture of powder, shells, bullets, shot, loading, reclaiming, testing, plating, detonating mixtures, and primers.

Dr. Carey P. McCord discusses the potential health hazards in the various processes in which several thousand persons are concerned.—*Industry Rep.*, V, 1: 1–12 (Jan.), 1930.

Industrial Medicine—Bernardino Ramazzini, in the years near 1690, laid the foundations of industrial medicine and has become its patron saint. In his "Diseases of Artificers and Trades-

men," published in 1700, he considered in 43 chapters the occupational ills of many types of tradesmen and even some of the professions. At that time there was, comparatively, a small number of dangerous chemicals but he described them with surprising insight.

Today the complex chemical intoxicants are so numerous that they may not even be enumerated. Said Ramazzini:

If we consider what a vast difference there is between the Europeans and the Americans, and other barbarous nations of the New World, we can't but be sensible that mechanik arts have contributed very much towards the civilizing of mankind.

Today, the foremost objectives of industrial medicine are:

1. To fit every person to types and quantities of work according to his ability, and without injury to himself or fellow workmen, and with profit to all concerned
2. To maintain fitness for work both as respects the individual and his environment
3. To educate the worker, particularly in personal hygiene and accident prevention.
4. To reduce absenteeism in any way related to health

Medical care of entire communities in mining areas or kindred enterprises, through contract arrangements, with the family as the unit, may lead to organized or socialized medical care, but it is not within the scope of industrial medicine. The layman's activity to turn the bad by-products of human impairment in industry into profit succeeds only when he does so through skilled industrial physicians. Industrial medicine should be neither purely "fraternal" nor "paternal." It must deal with the worker as a producing unit and not as a social unit. It centers about the factory and not the home. Its activities partake of the practice of both public health and curative medicine, and it deals with workers as individuals and in groups. Essentially conceived in selfishness, industrial medicine culminates in humanitarianism.

The need is great for organized medicine (1) to mark the just and proper domain of acceptable industrial medicine, (2) to stimu-

late a demand for the truly qualified industrial physician, and (3) to limit industrial medicine wholly to the boundaries set forth. If industrial medicine becomes merely a pathway to general care of all the sick by poorly educated, low salaried medical "hacks" it will defeat the very need by which it came into being.—

Editorial, *J. A. M. A.*, 94, 1: 33-34 (Jan. 4), 1930.

Western Electric Company Experiment—During the past two years, Elton Mayo and officials of the Hawthorne Works of the Western Electric Company in Chicago have been conducting experimental investigations of rest periods, working conditions, and other influences affecting workers. The investigators showed, at least tentatively, and in highly mechanized and repetitive operations, that—

1. Total daily output is increased by rest periods and not decreased.
2. The conditions of work during the working day have more effect on production than the number of working days in the week.
3. "Outside" influences, i.e., conditions not directly relevant to the task, tend to create either a buoyant or depressed spirit which is reflected in production. A distinct relationship is apparent between the emotional status of the workers and the consistency of their output.
4. The method of the supervisor is the most important single "outside" influence. Home conditions may affect the worker and his work; and a supervisor who can "listen" and not "talk" can in many instances almost completely compensate for such depressing influences.
5. Pay incentives do not stimulate production if other working conditions are wrong.

The most important and significant result is that dealing with the method of supervision. It was found that "bully-ragging" methods of supervision not only depressed workers but their production. It was found that workers came to increase their liking for their jobs with the new kind of supervision which substituted sympathetic "listening" for officious "talking," with a consequent increase of production.—*The Human Factor*, VI, 1 (Jan.), 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Effect of Cod Liver Oil Feeding on the Calcium and Phosphorus Content of Cows' Milk—While it has been definitely shown that the vitamin D content of the cow's milk can be increased by appropriate feeding and sunlight and that the retention of calcium and phosphorus is improved, the reports are conflicting as to the effect on the quantity of calcium and phosphorus in the milk and their relationship. In the course of investigations which have been lately reported, an opportunity was afforded to analyze milk for calcium and phosphorus during certain test feeding periods.

Short-horn cows were given a maintenance ration of hay and sugar pulp and a milk production ration consisting of various meals, corn and oats so that 3½ lb. of the mixture contained 2½ lb. of starch equivalent and 0.6 lb. protein equivalent. With this diet the milk of each animal remained unchanged for 4 or 5 months.

The experiment consisted of 6 periods: (1) normal diet; (2) 0.5 oz. olive oil per 3.5 lb. portion ration mixture fed; (3) 1 oz. olive oil per 3.5 lb. portion ration mixture fed; (4) 1 oz. cod liver oil per 3.5 lb. portion ration mixture fed; (5) 1 oz. olive oil per 3.5 lb. portion ration mixture fed; (6) normal.

Daily determinations of calcium in the milk were made and phosphorus determinations for each period on daily aliquots. The figures show no change in the percentage of calcium and phosphorus in the milk when cod liver oil is substituted for olive oil and neither oil effected a change over the normal diet. While daily fluctuations in calcium were

noted the total for the period for each cow was the same, and this with a constant milk yield over the period.

It was noted that the addition of cod liver oil materially reduced the percentage of fat in the milk.—Edmond John Sheehy and Brendan Joseph Senior, *Biochem. J.*, 23: 898, 1929.

The Influence of Different Samples of "Casein" on Vitamin Tests—Previous work from this laboratory has shown a difference in nutritional characteristics of two commercial varieties of casein (Abstract *A. J. P. H.*, 20: 213, Feb., 1930). This work records direct comparison of two types of commercial casein, "light-white casein" and "vitamin-free casein," designated respectively as "Casein B" and "Casein G." "Light-white casein" contains 2 to 3 per cent of fat which was extracted with alcohol and ether to insure absence of vitamin A. One-half of each of 5 litters of rats was given "Casein B" and the other half "Casein G," vitamin D being supplied with irradiated ergosterol. At the cessation of growth cod liver oil was administered.

The growth curves show the following points: All rats on "Casein B" maintained steady weight and responded to cod liver oil. Two of the litters on "Casein G" grew similarly, indicating the possibility of reserves in the rats or the adequacy of the casein in these two cases. The last 3 litters on "Casein G" did not respond in growth or to the addition of cod liver oil, indicating less reserve factor or inadequacy of the protein. The authors attribute the discrepancy to either the presence of a

heretofore unrecognized factor in one casein or to a different biological property, digestibility or assimilability.

The point is made that in an assay for vitamin A attention should be paid to the source of protein and the present U. S. P. assay for vitamin A is criticized since in the light of this experiment results might be discordant. It is suggested that for comparable results on vitamin A test a standard laboratory material should be agreed upon.

These two types of casein were further tried in vitamin B tests in which the casein, dextrinized rice starch, agar-agar, salt mixture and cod liver oil were used with the rats on screen-bottomed cages. After 11 days of this diet, amounts of dried yeast equal to 2, 5, 8, and 10 per cent respectively in the diet were given with no growth after 10 days.

The "Casein G" in the test diet was substituted by "Casein B," which was shown to be free from vitamins B₁ and B₂. A control not receiving dried yeast died in 3 days and two rats receiving 5 and 10 per cent dried yeast grew rapidly to 140 and 210 gm. weight. A rat with 8 per cent dried yeast and the "Casein G" diet grew but much less than the one with 5 per cent yeast and "Casein B."

The results were practically duplicated when marmite was used instead of dried yeast. Other experiments indicated that the yeast had its usual vitamin B potency, suggesting that the different results are due to a factor present in one casein and not in the other and that various litters had different reserves of the unknown factor or different powers of utilizing "Casein G."—Katharine Hope Coward, Kathleen Mary Key, Barbara Gwynneth Morgan and Marjorie Camden, *Biochem. J.*, 23: 913, 1929.

The Epidemiology of Paratyphoid Infections—A comprehensive resumé of the most recent knowledge of this enteric

group as presented in the Cutter Lecture in Preventive Medicine at the Harvard Medical School on March 28, 1929, forms the basis of this paper. The tangled condition of the nomenclature is discussed and the group classifications limited to a less confusing and workable basis.

Comparison is made of the means available for diagnosis of paratyphoid infections with conclusions that the only sure means of diagnosis is the isolation and identification of the specific bacterium involved rather than dependence upon serological tests. The unreliability of agglutination tests with serum from patients is stressed.

A critical study of the frequency or incidence of paratyphoid infections indicates a far greater proportion of paratyphoid carriers as compared to typhoid carriers than has generally been supposed. It is indicated that from one-fourth to one-half of so-called typhoid fever is really paratyphoid infection. Considerable attention is given to the differentiation of the various types included among the *Salmonella* and the confusion prevailing within this genus due to inadequate differentiation which has given rise to many of our present epidemiological uncertainties with respect to the existence of various "types" or species.

The epidemiology of paratyphoid infection is discussed under the head of specific types that have been fairly definitely implicated in the causation of human illness. The types included in the discussion were *S. paratyphosus* (A), *S. Schottmülleri* (B), *S. aertrycke*, *S. enteritidis*, and *S. cholera-suis*.

There were some types mentioned such as *S. abortivo-equinus* and several bacilli of avian paratyphoid that have not been clearly associated with infection of man.

The main sources of infection by organisms in this group are divided on the basis of human and animal origin. *S.*

paratyphoid (A) and Type B *Schottmülleri* are given as human parasites with which the lower animals are seldom if ever infected. In contrast to these two types the *aërtrycke*, *cholera-suis* and *enteritidis* strains seem to be primarily related with animal infections. This distinction, however, cannot be drawn too fine as it is known that some of the latter strains can cause disease in animals, give rise to food poisoning as well as occasionally cause active infection in man.

Attention is called to the epidemiologically significant fact that Types A and B commonly display invasive qualities, often entering the blood stream, while the animal paratyphoids are rarely invasive and are important pathologically mainly because of their ability to produce absorbable toxins.

Experimental work on the toxic products of this group of organisms is discussed and attention is given to recent work with heated culture filtrates that were fed to animals for the purpose of reproducing symptoms of "food poisoning." While apparently the toxic filtrates were not materially impaired by heat treatment as indicated by intravenous or intraperitoneal injection into laboratory animals, negative results were obtained when similar material was used in feeding tests.

In discussing the degree of protection afforded by vaccination against infection of the members of this group it was considered probably safe to assume that vaccination with the A and B types gives about the same degree of protection as that conferred by antityphoid vaccination, but there is no reason to suppose that any material protection would be conferred by the addition to so-called triple vaccine of *aërtrycke* and other closely related strains.

The lecture concludes with a review of the most recent knowledge of experimental epidemiology bearing on the spread of paratyphoid infection in man

and animals and discusses the measures likely to be most successful for control of paratyphoid infections of human and animal origin.—Edwin O. Jordan, *J. Prev. Med.*, 3: 279 (July), 1929.

"Food Poisoning" Produced in Monkeys by Feeding Living *Salmonella* Cultures—Rhesus monkeys fed with viable cells of two strains of the *Salmonella* group, *S. aërtrycke*, and *S. enteritidis*, manifested definite and characteristic symptoms of "food poisoning," watery diarrhea, general malaise with, in some cases, loss of appetite. Loss in weight was observed after 2 to 7 days.

Little if any immunity seemed to be produced by one attack of "food poisoning." A second attack could be produced in the same animal after a short interval. Monkeys fed with equivalent amounts of heat killed cultures showed no symptoms. Control feedings of living cells of *B. proteus* and *B. coli* were negative.—G. M. Dock, E. O. Jordan and W. L. Wood, *J. Prev. Med.*, 3: 153 (Mar.), 1929.

The Effect of Grape Juice on Nitrogen Retention and Urinary Acidity—The literature records both an increase and decrease in urine acidity according to the fruits ingested and there is some evidence that orange juice has a favorable effect on nitrogen retention. The present work deals with a commercial grape juice on a group of normal women.

In the first series, the basal diet of crackers, cheese, apple butter and almonds was supplemented by grape juice. In the second series, the basal diet was supplemented by grape juice in two experiments and by the caloric equivalent of the grape juice in glucose in two other experiments.

After a 5-day adjustment period, in the 3- to 4-day experimental period following daily nitrogen determinations of

urine and feces were made. In the first series the nitrogen retention was greater in the grape juice supplements. In the second series with equivalent energy diets the increase in nitrogen retention was insignificant—0.28 and 0.48 gm. compared to 0.98 and 1.11 gm. on the grape juice plus basal diet in the first series—indicating the nitrogen retention due probably to the sparing action of the carbohydrate in the juice.

In these series the urinary acidity remained almost constant. In one case there was a slight decrease, and in three a slight increase following grape juice addition, showing considerable quantities of grape juice have little or no effect on urinary acidity.—Louis M. Pickens and Rossleene Arnold Hetler, *J. Home Econ.*, 22: 44 (Jan.), 1930.

Hypervitaminosis and Vitamin Balance. IV. An Instance of Vitamin Balance—Only two references in the literature are cited as to the lack of balance between vitamin B complex and vitamins A and D or cod liver oil and one of these is the previous work of the present authors. In the former experiment large quantities of cod liver oil were administered and in the present experiment, oil concentrate. Similar basal diets were fed to matched sets of young rats supplemented by 1, 2, 4, 8, 16, and 32 per cent standard marmite extract. To each set cod liver oil concentrate at the rate of 2, 10, 50 and 250 mg. per 10 gm. of basal diet was added.

At the 1 to 2 per cent marmite level, 0.10 per cent concentrate did not stop the decline. At the 3.2 per cent mar-

mite level the addition of 0.10 per cent concentrate caused decline in weight but at the same level without concentrate rats were smooth-coated and did not decline in weight. Two animals on the 2.5 per cent concentrate died; controls receiving only 0.02 per cent concentrate remained well and grew. In the 8 per cent marmite level, optimal for ordinary diet, up to 0.5 per cent concentrate did not cause death but retarded growth. The 16 to 32 per cent marmite level concentrate up to 2.5 per cent was tolerated and two animals died.

The symptoms caused by excess of vitamins A and B parallel those with simple vitamin B₁ deficiency. The probability that the high doses of A and B concentrate are in any way poisonous is offset by the ability of the rats to withstand increased doses with increased marmite allowance. It appears more probable that the effect is not due to toxic action of vitamins A and D but to relatively inadequate vitamin B balance since the symptoms resemble B avitaminosis.

It is pointed out that vitamin D was administered at levels from 6 to 750 times the minimal physiological dose while other works have shown that a thousand times the minimal as irradiated ergosterol does not act unfavorably.

Vitamin A was increased from 200 to 25,000 times the minimum dose, hence the conclusion that the lack of balance is due to the vitamin A of the concentrate although the effect of other unidentified substances cannot be excluded.—Leslie Julius Harris and Thomas Moore, *Biochem. J.*, 23: 1114, 1929.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Miss Fox Goes to New Haven— The American Red Cross has announced the resignation of Miss Elizabeth G. Fox, the National Director of their Public Health Nursing Service, to take effect some time in May. She will become Executive Director of the Visiting Nurse Association of New Haven, Conn., and a member of the faculty of the Yale School of Nursing.

Miss Fox came to the Red Cross nearly twelve years ago as Associate National Director of Public Health Nursing. Since August 8, 1919, she has held the position of National Director of Public Health Nursing. A native of Wisconsin, she attended the University of Wisconsin where she attained high scholastic honors. Following her training at the Johns Hopkins School of Nursing she held key positions on the nursing staffs of the University Hospital, University of Minnesota; Chicago Visiting Nurse Association; Dayton, O., Visiting Nurse Association; and the Visiting Nurse Society, Washington, D. C.

Miss Fox has at one time or another served in high elective or appointive positions in most of the local, national and international nursing associations with which she has been identified. In Washington, D. C., she was president of the Graduate Nurse Association and president of the Board of Nurse Examiners. She has been president, also, of the National Organization for Public Health Nursing; chairman of the Public Health Nursing Section of the American

Public Health Association; and a member of the Nursing Advisory Council of the League of Red Cross Societies.—Letter to Red Cross Nursing Field Representatives by the American Red Cross, Feb., 1930.

The Public Health Nurse and Social Hygiene—Late last summer, through a financial arrangement with the American Social Hygiene Association, Edna L. Moore was added to the professional staff of the National Organization for Public Health Nursing, as Assistant Director. She will concentrate her efforts on interesting and educating public health nurses in the problems of social hygiene. In the January, 1930, *Public Health Nurse* she says:

The public health nurse, because of her established position in the community and her intimate contact with the home, has many opportunities to reach out into this field where educators are giving such splendid leadership. To grasp these opportunities and accept the responsibilities they carry, demands, primarily on the part of the nurses, an attitude of understanding and acceptance toward sex problems.

She goes on to say that the venereal disease question is a health question from our point of view, and it should be treated as such without confusing it with the idea of reform, because if men or women suffering from venereal disease sense in us the idea that their condition implies an act utterly reprehensible to us, we cannot hope to gain their confidence or help them to help themselves.

Up to the present time the public health nurse has played a small part in the venereal disease control program, and Miss Moore thinks it is because of inadequate preparation combined with

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

lack of leadership and too many other duties. We need specific answers to three questions:

1. How is community health affected by syphilis and gonorrhea?
2. What are the community resources to find and treat those affected?
3. What, precisely, can public health nurses do about it?

Some suggestions are given as to how public health nurses can help: Develop and extend prenatal work, as too many obstacles separate the expectant mother from diagnosis and the pregnant syphilitic woman from adequate treatment.

The public health nurse has many opportunities to discover congenital syphilis and avert some of its tragedies in her preschool, school and industrial nursing work.—Edna L. Moore, *The Place of the Public Health Nurse in Social Hygiene*, *Pub. Health Nurse*, XXII, 1: 32 (Jan.), 1930.

The Institute for Lay Boards in Chicago—This institute arranged by the Central Council of Nursing Education for lay boards of hospitals and public health nursing organizations was held at the Palmer House in Chicago, February 17.

The morning program was largely given over to public health nursing problems.

Edna L. Foley, R.N., superintendent of the Chicago Visiting Nurse Association, gave an address on "The Education of the Nurse from the Point of View of Public Health Nursing." She made five suggestions as to how the hospital nursing schools should prepare nurses for the public health field:

1. Prepare young women of *character*.
2. Give them certain fundamental essentials of social work.
3. Arrange for affiliation with a public health nursing association.
4. Arrange for lectures to arouse interest in patients as human beings.
5. Send nurses into this field who are socially adequate.

Miss Foley says the visiting nurse's motto should be—"Practice what you preach and teach at the same time."

Haven Emerson, M.D., of Columbia University, gave an address on "Public Health Nursing—Indispensable and Economical for Everyone if Organized," in which he stressed the need for the unification of all public health nursing services in a community in a generalized program as the only means of insuring an economical and really effective service. Following are some of the facts and suggestions from his talk:

The rating of health of 24 cities in the United States runs closely parallel to the number of public health nurses employed, and the death rate is not a good index of the public health work in a community.

In 24 cities in the United States, forty per cent of the public health nurses are serving 20 per cent of the population.

A city caring for 40 per cent of the defects of school children is going a long way toward tuberculosis prevention.

Thirty per cent to 50 per cent of clinic patients need mental hygiene more than anything else.

These are all arguments for generalized public health nursing services.

The nursing technic of the good visiting nurse associations is as adequate as that in the operating rooms of the best hospitals.

Michael M. Davis, M.D., of Chicago, in discussing Dr. Emerson's paper said that most of the money paid for the care of patients in a visiting nurse association came from life insurance companies. In 25 cities studied only two visiting nurse associations earned as much as 21 per cent of their money from fees from individual patients for service rendered; in 19 cities the fees from this source were less than 10 per cent.

Dr. Davis said that the way to increase the amount of money derived from direct service is to present nursing service through community chest and visiting nursing association campaigns in terms that are *not* charity,

yet, at the same time, insuring free care for those unable to pay.

A High School State Board of Health—The following program has been worked out for a senior high school board of health only this year, in the Morton Senior High School at Richmond, Ind. Because of the general educational trend which we hoped it would take it was patterned after the State Board of Health, rather than the City Board of Health. One member from each of the 40 assembly rooms was elected by his group to membership on the board. From this representation were elected a president, vice-president, secretary, and 4 division chairmen. The divisions were named health and hygiene, communicable diseases, vital statistics, and sanitation. Each member of the board was appointed to serve on one of these divisions. The dean of the high school is faculty sponsor, and the school nurse, who is Director of Public Health Nursing in Richmond and

Wayne County, is professional sponsor. Each division has a faculty adviser; i.e., the biology teacher is adviser for the division of communicable diseases; the chemistry and physics teacher for the division of sanitation. The vital statistics division is sponsored by the teacher of printing. The work of the health and hygiene division is sponsored by the French teacher, whose particular interest is in personal hygiene.

The board meets monthly to hear reports from the division chairmen, make plans for future projects, and discuss health problems. Division meetings are held at the call of the chairman not less than once monthly. A report of the meeting is sent to each teacher the following day, this report to be posted where her advisory group can read it.

The results have justified the existence of this organized effort and the board of health bids fair to become a potent factor in the development of a health consciousness in the school.—Virginia Jones, R.N.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Joyous Living Longer in Syracuse—The new radio "club" was announced as follows:

A Live-A-Little-Longer Club is being started in Onondaga County. Its object is to enable its members to be as healthy and strong as Jack Dempsey and Helen Wills, as beautiful as Apollo or Billie Dove and as old as Methuselah.

Membership is open to everyone, young and old alike, even including bald-headed men who have lost all their teeth. The preliminary announcement about this new organization states that it does not cost a single red cent to join. Its rules for avoiding sickness and for prolonging life are to be as free as the very air that people breathe.

During the past half century the average age of the American people has been raised from 40 to 57 years. The announcement states that there is every reason to believe that the average length of life can be still further extended.

The Club is sponsored by the Health Educational Division of the Onondaga Health Association. The meetings of the Club will be held at 6 o'clock each Wednesday evening and will last only about five minutes. Those desiring to join are invited to tune in on WSYR, Hotel Syracuse Broadcasting Station, promptly at 6 o'clock each Wednesday.

Education in Clinics—At Boston, June 9, at the National Conference of Social Work, will be continued the discussion of health education in clinics which was started at the A. P. H. A. meeting in Minneapolis.

Please help by sending samples, photographs, answers to the following questions:

Do you use exhibits? What are they? Where do you display them?

Do you use posters or placards? Where secure them, or do you make them?

Do you use slides or film-slides?

What do you have for people to read? Do you use scrap books or printed matter mounted in any fashion?

What else do you use, or do? What do you like, or object to?

Examples of devices and material will be shown at this session of the Health Division. Address your contributions to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Health Demonstration Before Rotary Club—A Georgia Health Center asks for ideas to be forwarded via editor of this department:

We have been asked to put on a program for the Rotary Club at a luncheon meeting. Last year we gave demonstrations of the actual work carried on at the Health Center, to which they contribute.

The Health Center Program consists of visiting nursing, clinics (curative and preventive), milk depot, baby stations, and school nursing service. If you could give us any suggestions for this program, we would appreciate it very much indeed.

More Statistics in State Press Releases—Another group of the lead paragraphs from Illinois press releases illustrate possibilities in effective use of statistical data. The full release in many cases could be adapted to other states, and with further changes could be adjusted for large city use.

Springfield, February 12: Mistaking symptoms for disease and treating terminal instead of incipient conditions account for a major part of Illinois' \$120,000,000 annual sickness bill. This, according to Dr. Andy Hall, state health director, is proved by an experiment with 6,000 individuals which shows an 18 per cent reduction in mortality as a result of annual medical examinations during apparent good health.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

"The experiment shows that 6,000 policy holders of a certain insurance company were given annual medical examinations over a period of 10 years," said Dr. Hall. "This group, selected at random, enjoyed an 18 per cent better mortality experience than the other policy holders in the company of comparative age. In economic terms the 6,000 individuals got \$3.00 back in the form of extended earning time for each \$1.00 spent for the examinations."

Springfield, February 19: By far the highest decline in nearly a decade marked the course of mortality from tuberculosis in Illinois last year. This statement was accompanied here today by an announcement from Dr. Andy Hall, state health director, that April will be devoted to an extensive campaign against tuberculosis in children, the great seed-bed of the disease. At last year's rate of decrease, tuberculosis will practically disappear from the state in 25 years.

"Provisional figures show that mortality from tuberculosis reached a new low level in Illinois last year when 5,248 deaths gave a rate of 70 per 100,000 population," said Dr. Hall. "This is 4 per cent below any previous rate ever registered in the state, while the degree of decline was greater than for any year since 1921. The actual number of deaths fell 200 below the 1928 figure while the population is estimated to have increased by 82,000. The decrease last year in tuberculosis took place in Chicago as well as down-state."

Springfield, March 5: An expanding practice of birth control on the one hand and a growing effectiveness of disease prevention on the other are indicated in statistics made public here today by Dr. Andy Hall, state health director, which show sharp declines in the birth and mortality rates for Illinois last year.

The number of births in the state last year fell a full thousand below the 1928 figure, giving a rate of 17.2 per 1,000 population, the lowest rate on record in Illinois. Deaths dropped 2,403 under the number for 1928, giving a rate of 11.7, one of the most favorable on record.

The 128,634 births and the 87,789 deaths registered in the state last year gave an excess of 40,845 births over deaths. This figure gives a net increase in population from this source of about one-half of one per cent and adds about one person per square mile to the density of population.

Excess of births over deaths in Illinois has dropped from 71,228 in 1921 to 40,845 last year, a fall of 42 per cent in the ratio. In the face of an increasing population the actual number of births has declined from 144,637 in 1921 to 128,634 last year, a drop of 11 per cent.

The continued fall in the birth rate, which involves the best elements in the population much more than the worst, would be a cause of distinct alarm were it not for the somewhat compensating influence of preventive medicine. . . .

Social Work Publicity at Boston in June—At the National Conference of Social Work, the Health Division will have one education-publicity session; Educational Publicity Division, 5 morning sessions; and Social Work Publicity Council, 10 luncheon, afternoon and dinner sessions, with several simultaneous round table groups. Public health workers make up the largest membership group in the S. W. P. C., so that a goodly number of live health workers will be at Boston. Frank Kieran, Massachusetts Tuberculosis Association, is the Boston local chairman for the publicity group.

The Beginnings of Health Education-Publicity—When did popular health education begin? When did one or more forms of publicity become generally accepted as a phase of public health?

These and related questions have been raised recently by several editors and writers. What can you dig out of the past? Please write to editor of this department. Samples of the earliest publicity of any kind—from 10 years ago, or 20 years, or further back—will be received with much appreciation.

New England Health Institute—Meeting in Boston, April 14-18, the Public Health Education Section under the chairmanship of Ira V. Hiscock will present the following:

Training for Health Education—C. E. Turner, Richard Schmoyer; Printed Matter Clinic—R. S. Patterson, H. E. Kleinschmidt, P. E. Gillingham, Harford Powell, Jr.; Health Education—Mabel Bragg, Ernest Stephens; School Health Education and Public Health—M. L. McWilliams, Fredrika Moore; Planning an All-Year Round Program on Health Publicity—M. S. Routzahn, F. L. McKay; The

Place of Health Education in Normal Schools—F. W. Wright, J. A. M. Andress; Individualization in Public Health—R. C. Cabot.

Section on Vital Statistics will have: Annual Reports Use and Abuse—I. V. Hiscock, Charles Duncan; Use of Statistical Tracts in Planning Health and Social Propaganda—Iago Galdston, J. J. Balf.

A Division of Public Health Education—The recently issued report on 1928 health education by the New York State Department of Health tells of a surprising amount and variety of the educational work. The main topics covered are: radio talks, newspaper use of radio talks, the weekly bulletin, newspaper publicity, correspondence course for nurses, conference of health officers and nurses, exhibits and motion pictures, lectures, correspondence, Department publications, mailing room activities.

In handling requests for information much use is made of the mimeographed press releases of the radio talks. A list of 51 radio talks is given in the report. *Free.*

Again General Warnings Are Questioned—Under "Too Much, or Too Little" (Oct., 1929, page 1171) we quoted *Editor and Publisher* in criticism of health warnings against unidentified products. Another point of view is expressed by F. P. A. in the *New York World*:

Our belief is that Dr. Wynne's so-called war on radio broadcasting by so-called fake medical advertising is toothless. What are the concerns that Dr. Wynne thinks broadcast fake medical advertising? What are some of the alleged quack remedies advertised? Are they harmful, or habit-forming, or both?

Photographs Wanted—Several book publishers are seeking photographs illustrating health conditions or health education methods. If you have good photographs to offer, please tell the ed-

itor, and write George H. Betts, School of Education, Evanston, Ill., for the list of 46 subjects wanted for a revision of the Emerson and Betts Health and Hygiene Series to whom "any striking health activity or safety measure will be acceptable." You get credit *and cash.*

Forms of Printed Matter—For the benefit of writers who are confused in their use of terms to apply to various types of printed matter, it seems desirable to reprint some definitions.

Handbills—"The handbill or dodger is a single sheet printed on one side which is handed to people on the street, dropped into house mail boxes, thrown on doorsteps, or posted in public places. . . . The handbill is usually small enough (about 6 by 9 or 8½ by 11 inches) to be carried in the hand and large enough to be posted on a wall or bulletin board."

Further discussion of the place of the handbill in the publicity scheme, and how to make it most effective, will be found in *Publicity for Social Work.*

(Further definitions next month.)

Propaganda—"Propaganda," says Edmund B. Chaffee, "has been used as far as we can learn by every great social, political and religious movement which the world has known."

But just what is propaganda? The *Encyclopedia Britannica* defines it as "a concerted scheme for the promotion of a doctrine or practice, more generally the effort to influence opinion." This is the *Encyclopedia* definition but possibly we can get at the real meaning to the average man by saying that the essence of it consists in the spreading of reports and deductions from them for the purpose of influencing public opinion and conduct. These reports, of course, may be true, partly true, or false. They may be by word of mouth or the printed word. They may spring from good motives or from bad. These things make no difference as far as our word is concerned. The word propaganda covers any deliberate effort to disseminate information for the purpose of influencing conduct in the direction desired by the propagandist.

Then follows an interesting discussion of "Ethics and Propaganda," in *Unity*, 700 Oakwood Blvd., Chicago, Ill., Feb. 3, 1930. 15 cents.

RADIO

New York State Department talks: Security and Mental Health, Modern Magic (prevention of babies' sore eyes), A Horoscope for 1930-1931 (the "signs" of health).

The U. S. Public Health Service has issued these talks: Some General Dietary Hints, Heart Disease and Its Prevention, Preventing Diseases of the Teeth and Gums. (Much good material after the "big words" have been eliminated.)

The Department of Health of New York City has broadcast on the following: How to Get Fat, Facts About Quacks, Winter Exercise, The Common Cold, Tuberculosis—Early Discovery—Early Recovery (about 2,300 words each).

The series of radio talks on radio quackery, broadcast by the Health Department of New York, will be supplied upon request.

Broadcasting by the Connecticut State Department of Health has been changed to 12:00 noon (Eastern) on Thursdays. Station WTIC.

The Live-A-Little-Longer Club, Onondaga Health Association, Syracuse, holds its weekly meetings via radio at 6:00 p.m., Wednesdays. Station WSYR. The opening session has been mimeographed for distribution.

The House Fly, several mimeographed sheets, provides broadcast material or copy for other uses. Lively and very frank as to fly filth. Address Rutherford County Dept. of Health, Murfreesboro, Tenn.

See also "Dates Ahead."

DATES AHEAD

April—Early Diagnosis Campaign. Address National Tuberculosis Association, 370 7th Ave., New York, N. Y.

A variety of materials and suggestions are available. Especially interesting is the "Manual" which is supplied in one booklet, or in three booklets divided for workers with physicians, school groups, and parents and the public.

April 14-18 (Monday-Friday)—New England Health Institute, Boston. With various publicity sessions. Address George H. Bigelow, Dept. of Public Health, Boston, Mass.

April 17 and 24 (Thursdays)—Broadcast by American Junior Red Cross via Columbia System. The program:

With a cast made up of Juniors assisted by a professional character actor the program will demonstrate a Junior council meeting attended by a physician who, at the request of the council, has made a study of health conditions in the community and the school. The Junior council receives the doctor's report, comments on various phases of it, and develops with his help the remedies for the undesirable health conditions which exist in the town.

April 26-May 3—Boys' Week, with Tuesday, April 29, as "Boys' Day in Schools and Health Day." Address National Boys' Week Committee, 211 West Wacker Drive, Chicago, Ill.

May 1 (Thursday)—May Day and Child Health Day. Address American Child Health Association, 370 7th Ave., New York, N. Y. Special material includes: pageant, poster, Festival Book, Play Day—The Spirit of Sport, Teamwork for Child Health, Child's Bill of Rights, recreation poster, a simple musical pageant, cuts or mats of May Day seal, and a series of mimeographed sheets of suggestions.

May 7-10 (Wednesday-Saturday)—National Tuberculosis Association, Memphis, Tenn. With a critique of printed matter by Douglas McMurtrie of Chicago, and a demonstration of the Tuskegee travelling health school.

May 12 (Monday)—National Hospital Day.

May 18-21 (Sunday-Wednesday)—Advertising Federation of America,

Washington, D. C. Address at 420 Lexington Ave., New York, N. Y.

Armstrong. Reprint from *Long Island Medical Journal*. 5 pp.

DIPHTHERIA

"Children Who Might Live," by W. W. Bauer. *Hygeia*. Mar., 1930. Popular article.

"The Study of Poster Art Advances," by Z. B. Kimmey. *Poster Magazine*, Chicago, Ill. Jan., 1930. 35 cents. Based on New York's high school poster contest. 4 diphtheria posters illustrated.

"Diphtheria in Ansonia." *Weekly Health Bulletin*, Connecticut State Department of Health. Mar. 3, 1930. Striking 10-year comparison of an anti-diphtheria city with two neglectful ones.

Announcement of the second New York State diphtheria poster contest. S. C. A. A., 105 East 22d St., New York, N. Y. 8 pages. Free. A happy idea is that the committee supplies the text (5 alternative forms) to appear on a poster.

Report blank for a local campaign prepared by the State Charities Aid Association, 105 East 22d St., New York, N. Y. 4 pages, 9 by 12 inches. Includes statistics, campaign organization, details of house to house canvass, organization of clinics (including details of equipment to be checked), publicity, how various groups coöperated, etc. A campaign could be planned with no other instructions. With a few changes could be used in any state or county. Free.

EDUCATIONAL MATERIAL

The following have been issued by the Metropolitan Life Insurance Co., New York (free):

The Board of Health—What it can and should do—with your support. 14 pp.

Overweight and Underweight—How to Treat Them. 32 pp. Menus, reducing exercises, weight reducing record.

What Is Rheumatism? 12 pp.

The Education of Insured Groups, by D. B.

Other sources:

New York Tuberculosis and Health Association, New York, N. Y.: How to Tell What in Popular Health Instruction, by Iago Galdston. Reprint from *A. J. P. H.* 4 pp. Free.

Superintendent of Documents, Washington, D. C.: Nine charts on nutrition and growth—pictures showing effects of adequate and inadequate diets on laboratory animals, prepared by Bureau of Home Economics. 50 cents.

Superintendent of Documents: Heart Disease a Public Health Problem. Reprint, 5 pp. 5 cents.

PRESS RELEASES

Recent press releases of state departments have covered the following topics: Child Health Conferences, Parrot Fever, Getting the Camps in Shape (Md.); Disinfection, Scarlet Fever, Sinus Disease (Ore.); Additional Water Safeguard for Travelers (Conn.); Tuberculosis on the Toboggan, Health of the State—February, Bottled Sunshine for Dark Winter Days, Winter Deaths from Heat, Carbon Monoxide Poisoning, More Measles Coming (Ia.); State Health Department Files 50th Report, Empty Sanatorium Beds Are Costly (N. Y.).

The U. S. Public Health Service has been running an extended series of releases based on the annual report and special reports of the Service.

Detroit has discussed the following: Smallpox is increasing, where Are Detroit's Tuberculosis Cases?

New York City offers a weekly review of The City's Health; also Street Sales of Uncovered Pretzels, Parrot Fever, New Serum for Pneumonia, Sixteen New Health Centers, Charter Change to Hush Noises.

MOTION PICTURES

"The Girl Scout Trail," a new Girl Scout picture, is supplied free through Visugraphic Pictures, 247 Park Ave., New York, N. Y.

BOOKS AND REPORTS

A Book of Crimes—By A. S. MacNalty. London: Elkin Mathews and Marrot, Ltd., 1929. 328 pp. Price, \$3.50.

The author has given the histories of twelve crimes, some famous and some little known, of the 17th, 18th, and 19th centuries—historically correct in many respects, though here and there interwoven with some romance. He is a facile writer, using language sometimes quaint, but always interesting.

The psychology of the crimes is interesting. From the medical standpoint, the description of the poisons used and their effects are the chief points.

The book can be recommended to all interested in criminology, and will serve to pass away a number of hours in an interesting manner for the average physician.

M. P. RAVENEL

Disease and the Man—By George Draper. New York: Macmillan, 1930. 270 pp. Price, \$4.50.

In this new volume Draper has attempted to round out his earlier studies, published in 1924 under the title "Human Constitution." Most of the chapters consist of revisions of previously published papers representing his conclusions after 5 years additional experience with the Constitution Clinic of Columbia University.

The author, in his preface, states that in considering disease, it becomes essential for a complete understanding of any given case to understand the man himself. To do this successfully involves an investigation, not only of the usual clinical examination, but also of the four principal contributing factors: The mor-

phological, physiological, immunological, and psychological aspects of the man. He emphasizes his belief that these four panels of personality are all coördinates in determining the susceptibility of the individual to any particular disease.

The book, as a whole, is one of unusual interest. Its texture, however, appears somewhat uneven. In some places the author is extremely technical; in others he descends to a frankly "lay" style. The result seems neither quite "scientific," nor quite "popular." Its chief fault technically is its lack of coherence, with considerable unnecessary repetition, apparently the result of merely collecting and reëditing a series of more or less loosely related studies, rather than attempting to rewrite the material into a unified whole.

The chapters on morphology and genetics are the most thorough and valuable. It is with this field that the author is primarily concerned, and the detailed discussion, particularly of his gastric ulcer and gall bladder types, is most revealing of the scope of his methods of investigation. In the chapter on the influence of sex, he has gathered a considerable amount of interesting material of somewhat elementary nature, and demonstrated its applicability to a small, rather carefully selected group of cases, in support of his hypothesis.

In his chapter on the psychological panel he has delved largely into standard works of other investigators and shown the value of such methods as a means of approach to the study of certain cases. His immunological panel is still largely in the speculative period, as there is very little scientific evidence at hand to support more than the most

theoretical consideration of its significance in respect to disease. The importance of correlating these various aspects of the individual in relation to the specific disease problem is well brought out, and the need of much further work in this direction indicated.

The book is one which should reach a fairly wide and discriminating public.

LAWRENCE W. SMITH

The Road to Health—By *John P. Koehler, M.D. Milwaukee Health Department*, 1929. 85 pp. Free.

Hats off to the Health Officer of Milwaukee! He has written a booklet on personal hygiene, which is published by the local health department and distributed free, presumably to the residents of the city. Fitting the pocket and only 85 pages in length, it still covers adequately the familiar ground of healthful living.

Captious critics might wish for more color and warmth in make-up and text. Other health officers will read it and convince themselves that they could do better. Let them try! Public health would receive a great impetus if others would attempt the publication of such a booklet and do half as well.

R. S. PATTERSON

Health Work in Soviet Russia—By *Anna J. Haines. New York: Vanguard Press*, 1928. Price, \$.50.

This little book is one of the *Vanguard Studies of Soviet Russia*, edited by Jerome Davis of Yale University. It is the result of a study extending over several years during which the author had abundant opportunity for observation.

Some of the outstanding points brought out are that the Russian of today regards physical health as important a factor in life as education; that doctors are limited to a working day of 6 hours; that all workers in medical institutions, including doctors,

nurses, orderlies, laundresses, stove men, chauffeurs, etc., are organized into the *Medical Workers Union*; that there are night sanatoriums for tuberculosis; and that the infant mortality rate dropped from 27 per 100 in 1913, to 17 in 1923.

The author holds that the Soviet Commissariat of Health has made a real contribution to the administration of the world's work, and that its influence on medical work in Russia is very real. She evidently believes that a better acquaintance will spread its influence to other countries. In Russia the emphasis on medical education has been shifted from laboratory research to practical service, though abundant time and opportunities are given for research.

Russia has for a number of years been such a closed country to the average person that one finds it difficult to evaluate the statements of the author, who has evidently become enthusiastic over the work done in that country.

M. P. RAVENEL

Healthful Living. The Why and the How—By *S. E. Bilik, M.D. New York: Scribner*, 1929. 261 pp. Price, \$2.50.

Another book on the perennial subject of personal hygiene needs some distinguishing marks if it is to escape engulfment in the profusion of literature on this topic. This one is written in a breezy style which is neither difficult to peruse nor to comprehend. It has color and individuality and the author is outspoken in giving his own opinions, most of which, however, are sound and free from faddism. He admits having been inclined at one time or another toward various fads and even cults, but to his credit he has emerged from all such erroneous ways and the result, as printed here, is a commendable piece of work.

The usual material on personal hygiene is included. There is an excellent

chapter on exercise, a subject in which the author, as a former athletic director, seems particularly proficient. There is also an interesting discussion of the healing cults, which by its frankness and freedom from abuse demonstrates that the regular practitioner is the only safe general healer. The remainder of the book seldom rises above mediocrity in content, the chapter on diet, for example, being about the average in such books, or not quite fair in quality.

The lay reader would probably enjoy reading this book and would get much information.

JAMES A. TOBEY

Schistosomiasis and Malaria in Relation to Irrigation—By J. F. C. Haslam, M.C., M.D., M.R.C.P. Ed., D.P.H. London: His Majesty's Stationery Office, May, 1929. 52 pp. Price, \$.35.

This report deals with a subject of growing importance from the public health standpoint. As the population of the world increases, so must new lands be brought into cultivation, many of which require irrigation.

Schistosomiasis (endemic hematuria) is one of the most common of all diseases in certain parts of the world. It is said to be responsible for 25 per cent of the deaths in Egypt; while in some districts, 85 per cent of the agricultural population, and 54 per cent of the proprietors and artisans suffer from the infection. Indeed it is believed by some that these figures are too low. The building of dams and increase in the water supplies furnishes the water necessary for the life cycle of the causative worm. If the eggs do not reach water promptly, they die, and even when hatched, depend upon a fresh water snail as host. The increase of dams and reservoirs also furnishes a problem in regard to malaria, since water is needed for the life cycle of the mosquito.

The report is well done, and ends

with three appendixes, the first giving the geographical bibliography of reported cases of schistosomiasis, the second the relation of irrigation to climate and to nutritive value of crops, and the third the rules enforced in the irrigation concessions in the Sudan. While the report relates only to parts of the British Empire, it contains much that will be of value to sanitarians in every country in which these problems are present and increasing.

M. P. RAVENEL

Second Annual Report of Ohio Conference on Sewage Treatment—Held at Marion, O., October 31, 1928. Columbus: State Department of Health, 1929. 61 pp.

The second annual report of the Ohio Conference on Sewage Treatment, which was held in October, 1928, gives in the front abstracts of the papers and discussions. The papers include two on the operation of specific sewage treatment plants and one on the important subject of revenue from sewage sludge. On account of the importance of the Ohio sewer rental method of raising funds for sewage treatment and the general interest in this subject in the State of Ohio, some time was given to the discussion of this law. These are included in the report.

ARTHUR P. MILLER

Practical Handbook for Diabetic Patients—By Abraham Rudy, M.D. Boston: Barrows & Co., 1929. 361 pp. Price, \$2.00.

This book is an important addition to the large number of handbooks for laymen on diabetes. Dr. Rudy recognizes the important fact that all types of patients suffering from diabetes cannot be treated alike. Each patient has certain family and racial characteristics which must be taken into consideration in treatment for any disease, especially one so chronic as diabetes.

The native American, with minor exceptions, will eat almost any kind of

food. The people of the Jewish and Italian races among whom diabetes is most prevalent have developed many idiosyncrasies, habits, and distastes for foods, which must be taken into consideration. The physician cannot in a few days or weeks of treatment change the food habits of a patient, gained from many generations of ancestors.

Dr. Rudy gives an excellent number of menus for various races, particularly Jews. The system of substitution diets is very ingenious and should be widely used.

The format of the book dispels the layman's fear of technicalities. The type is large and clear and easily comprehensible. The book should be recommended to every diabetic.

REUBEN FINKELSTEIN

Report of the Westchester County Sanitary Sewer Commission, 1929

—This Commission, which was appointed by the Board of Supervisors of Westchester County, N. Y., in June, 1926, made an immediate study of sanitary conditions in the county and from that drew two main conclusions: (1) that the interior of the county, except for an area of 3 square miles in the Bronx Valley, was without adequate sewage disposal facilities and also without any real hope of relief other than through this Commission; (2) that almost all of the shore section discharged raw sewage into the Hudson River or Long Island Sound, either directly or through very limited treatment plants.

These conditions would have a decided effect on the growth of the county, because of the menace to health and on account of the established fact that a territory cannot reach its maximum growth without adequate sewage collection and disposal facilities. To correct the conditions found, the Commission is rapidly developing comprehensive plans. Four projects costing almost \$13,000,000 are either completed or close to

completion and the Commission's report to the Board of Supervisors on three other projects which will cost almost \$10,000,000 is awaiting the action of that board. A preliminary and approximate estimate of the final cost to complete a sanitation program in Westchester County is almost \$56,000,000. Such an expensive program as this is feasible only because the assessed valuation in this county is very high.

ARTHUR P. MILLER

The Hebrew Physician—*Moses Einhorn, M.D., and L. M. Herbert, Editors (Printed in Hebrew). 983 Park Avenue, New York. Vol. 1—No. 2, 1929–1930.*

The second issue of *The Hebrew Physician* (Harofeh Hoibri), the only Hebrew medical journal published outside of Palestine, has just made its appearance.

This consists of 180 pages, and contains numerous articles on general medical subjects, including a copy of the manuscript on "Hemorrhoids," by Shlomo Eben Ayub of Badrash, France (1265 A.D.). A special section is also devoted to new Hebrew medical terminology.

Home Nursing and Child Care—*By C. E. Turner, Dr.P.H., Nell Josephine Morgan, R.N., and Georgie B. Collins—Malden Health Series. Boston: Heath, 1930. 282 pp. Price, \$1.20.*

The authors, in their preface, mention that the material is not new "except in organization and method of presentation." We agree with them. They have included some very fine, practical knowledge, in logical sequence. The book opens with "What nursing means to the home," and continues with "Selection and care of the sick room." The chapter on symptoms is followed by methods of taking temperature.

It has splendid chapters on infec-

tions, antisepsis and control of communicable diseases. Personal hygiene of childhood and youth is treated in a sane, practical manner. Actual, scientific and usable facts are given, though it seems to us these might have been presented in a less businesslike manner. Perhaps the authors are relying upon the instructors to animate the subject matter. They mention, for instance, that it is safer to give an egg to a pre-school child for breakfast than for supper. If we were an adolescent we would like to know why. The book is filled with excellent, graphic illustrations; in fact, they actually "speak for themselves."

There are at present very few books which can be used as texts for students of home nursing and child care, whereas the demand to teach these subjects is growing by leaps and bounds. It seems to us that the majority of the textbooks available are too "grown up." This was written expressly for the upper junior and lower senior high school student and will, no doubt, be welcomed both by students and instructors of home nursing and child care.

HENRIETTA LANDAU

Handbook of Bacteriology for Nurses (3d ed. rev.)—By Harry W. Carey, M.D. Philadelphia: Davis, 1930. 282 pp., 43 ill. Price, \$2.25.

As ten years had elapsed since the second edition of this useful handbook appeared, it was found necessary to rewrite the entire work and to enlarge it to meet the more exacting requirements of the National League for Nursing and the State Boards of Education. The needs of nurses traveling beyond our national borders were likewise met by the inclusion of some of the more common foreign diseases.

The book consists of 20 chapters, a series of laboratory exercises and demonstrations, glossary and index. Virtually every phase of bacteriology is

treated with sufficient fullness to make it of value to many others than nurses. Bacteriophage has been omitted. The inclusion of chapters on bacteria in water and milk, pathogenic protozoa and diseases caused by unknown organisms makes this volume worthy of being on the shelves of all health officers and general practitioners. Of pedagogic value are the lists of review questions at the end of the various chapters.

Errors are exceedingly rare, but there is one in the illustration on page 197 where the male mosquito is designated as the female, and *vice versa*. However, this illustration is taken from Zinsser's well known text—where the same error is committed. Zinsser copied from Carroll, but the latter reference is not at hand to this reviewer.

C. F. ADAMS

Feeding the Family—By Mary Swartz Rose, Ph.D. New York: Macmillan, 1929. 476 pp. Price, \$5.00.

The third edition of Dr. Rose's eminently practical and authoritative text should prove, as the previous editions have, an ever-present help to any family. All of the valuable material of the first two editions is carried over into this very complete new volume. In addition, the results of the most recent research concerning the various vitamins brings the work up to date in that connection and in Dr. Rose's very direct, simple, live style which means much to the understanding of the lay mind. New diet lists have been made and the tables of calories and dietary recipes which appeared to be so complete in the earlier editions have been revised and made still more comprehensive in this one. Every age, type, and occupation is taken into consideration in these plans, as well as the cost of the food necessary to carry them out.

Out of the 15 chapters which the book contains, 6 are given over to the

food necessary to maintain the growth of the child from babyhood to youth. A chapter each is given to the adult man, the adult woman, and the man or woman "after 50." These form the body of the book. They are preceded by two introductory chapters on the significance of food in relation to the maintenance of the entire body and the care of the "Digestive Mechanism," and followed by 3 chapters given over to family menus, and cost of preparing those menus.

The concluding chapter is devoted to food for the sick and convalescent and answers many a puzzling question for the anxious member of the family who has to meet this problem. After this come 100 full pages of an appendix containing the calorie portions of everyday foods, dietary recipes that are both palatable and healthy, a table of calories to be found in different foods, the practical fitting of foods to the family pocketbook, and, at last, the height-weight tables for different ages so that the families may prove for themselves the value of eating properly for health.

The whole book is written in a most attractive style and made still more attractive by a number of full page illustrations, several of which are in color.

LENNA L. MEANES

The Medical Museum. *Modern Developments, Organization and Technical Methods Based on a New System of Visual Teaching*—By S. H. Daukes, O.B.E., M.D., D.P.H., D.T.M.&H., Director of The Wellcome Museum of Medical Science affiliated to The Bureau of Scientific Research. London: The Wellcome Foundation, Ltd., 1929. 183 pp.

Dr. Daukes has presented in a beautifully illustrated book methods of museum display and classification, with a reference list which includes the more important articles on museum technic. While the method of display shown in

the some 30 half-tone plates is not new, it is perhaps better worked out in its details than any other previous presentation. The book should be of value to all those concerned in museum work and the methods can also be adapted to other types of educational display, particularly along the lines of preventive medicine and public health.

MAJOR GEORGE R. CALLENDER

Pathogénie et traitement de l'asthme bronchique. *Mémoires couronnées publiés par l'Académie Royale de la Médecine de Belgique.* Vol. 24—By M. A. Haibe. 42 pp. 1929.

This investigation was awarded the Simont prize of the Royal Belgian Academy of Medicine. It deals with "bronchitic asthmas" though recognizing the larger group of responses designated as "asthma." Hemolytic streptococcus occurs in the expectorations of 80 per cent of bronchitic asthmatics. Intradermal injection is a valuable indicator for the determination of the antigenic rôle of the isolated germs. Injections of vaccine, repeated at the same point, create a local refractory condition which tends to become general when one injects each time at a new point in the skin. At first the injections of vaccine provoke a considerable afflux of polynuclears in the diseased parts of the lung. They stimulate a leucocytosis of the blood and they alter the blood count, often disturbed in asthmatics, in the direction of a neutrophile polynucleosis.

The autovaccine therapy dries up the source of the antigenic streptococcus and suppresses or attenuates the symptoms of bronchitis and asthma.

The hemolytic streptococcus plays an antigenic rôle of first rank in bronchial asthma. Autovaccines prepared with this antigen give favorable results with many asthmatics, and these results are incomparably superior when treatment proceeds without loss of time.

C. A. KOROID

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Age and Sex in Tuberculosis—Endogenous reinfection plays an important part in producing pulmonary tuberculosis in early adult years; waning immunity, environmental and industrial hazards are responsible for the disease in later adult life. These are some of the implications of this interesting article.

CUMMINS, S. L. Factors of Age, Sex and Occupation in Adult Pulmonary Tuberculosis, *J. State Med.*, 38, 2: 99 (Feb.), 1930.

Early Diagnosis of Cancer—Schemes for stimulating periodic physical inspections in order to detect cancer while still in the operable stage are discussed. The British viewpoint has several novel features not included in the typical American discussion of this problem.

DONALDSON, M. Early Diagnosis and Treatment of Cancer, *J. State Med.*, 38, 2: 88 (Feb.), 1930.

Physical Fitness Examinations—The relative importance of physical and social examinations are set forth in this discussion. "Health Examination" is a misnomer; the author prefers "Physical Fitness" for the good reasons given.

EMERSON, W. R. P. What is a Physical Fitness Examination?, *New Eng. J. Med.*, 202, 7: 330 (Feb. 13), 1930.

Postvaccinal Encephalitis—A detailed and accurate presentation of what is known of the cases of encephalitis following vaccination in England and Holland. This intensely interesting paper deserves careful reading by every sanitarian.

FLEXNER, S. Postvaccinal Encephalitis and Allied Conditions, *J. A. M. A.*, 94, 5: 305 (Feb. 1), 1930.

Dust and Tuberculosis—In the guinea pig it is possible to light up a quiescent tuberculous infection and render the focus progressive by dusting with siliceous dusts. Human cases need much more study than has thus far been given.

GARDNER, L. U. Will the Inhalation of Siliceous Dusts Activate a Partially Healed Focus of Tuberculous Infection?, *Pub. Health Rep.*, 45, 6: 282 (Feb. 7), 1930.

Undulant Fever—A valuable series of papers concerning such important questions as differentiation between *Brucella abortus* and *Brucella melitensis* infections, laboratory diagnosis, bacteriology.

GIORDANO, A. S., and SENSENICH, R. L. *Brucella Abortus* Infection in Man.

CARPENTER, C. M., and BOAK, R. A. The Laboratory Diagnosis of Undulant Fever.

LYNCH, F. B., and CALLAN, A. M. Some Observations on the Agglutination of *Br. Abortus*, *J. Lab. and Clin. Med.*, 15, 5: 421 (Feb.), 1930.

Correcting Case Rates—By determining the proportion of deaths from communicable diseases not previously reported as cases, one can correct the morbidity rate to that extent and thus make a more satisfactory fatality rate.

GREEN, H. W. Corrected Fatality Rates in Public Health Practice, *Pub. Health Rep.*, 45, 4: 169 (Jan. 24), 1930.

Streptococci in Milk—Specific directions are given for identifying *Streptococcus epidemicus* and the streptococcus of scarlet fever in milk. How these tests are used to safeguard certified milk is described.

HARDENBERGH, J. G. The Identification and Significance of Hemolytic Streptococci in Milk, *New Eng. J. Med.*, 202, 8: 373 (Feb. 20), 1930.

Poliomyelitis in Canada—Two good accounts of recent outbreaks of poliomyelitis (in Ottawa and Ontario) describe the methods of collecting and administering convalescent serum, and the results thereof.

LOMER, T. A., *et al.* Report of an Epidemic of Poliomyelitis in Ottawa, 1929 (and)

HARDMAN, R. P., *et al.* Poliomyelitis in Ontario, 1929. *Canad. Pub. Health J.*, 21, 2: 53 and 76 (Feb.), 1930.

Scarlet Fever Immune Serum—Contacts given scarlet fever immune human serum were protected to a sufficient extent to cause the author to recommend this prophylactic treatment of young and infirm contacts.

MEADER, F. M. Scarlet Fever Prophylaxis, *J. A. M. A.*, 94, 9: 622 (Mar. 1), 1930.

Measles Prophylaxis—Tunnick's antimeasles diplococcus serum protected three-quarters of the persons who received it within 5 days after exposure.

PETERMAN, M. G. Antimeasles Diplococcus Serum (Tunnick), *Am. J. Dis. Child.*, 39, 2: 294 (Feb.), 1930.

Rheumatic Fever—A good general review of the newer knowledge of rheumatic fever covering definition, course, incidence and care, written for nurses. This subject seems to have been considered now from every angle and for every group who might possibly be interested.

ROTH, I. R. On Rheumatic Fever, *Am. J. Nurs.*, 30, 2: 131 (Feb.), 1930.

Rabies Transmitted Through Milk?—Should persons drinking milk from a rabid cow be given the Pasteur treatment? The observations recorded lead to the opinion that the preventive treatment is not justified.

MUGRAVE, E. R. Milk-Borne Rabies, *J. Lab. & Clin. Med.*, 15, 5: 460 (Feb.), 1930.

More About Rheumatic Fever—Patients with mitral disease of the heart who have had rheumatic fever in childhood have a chest deformity which displaces the left nipple upward and outward from its normal position.

SCHWARTZ, S. P. Displacement of the Left Nipple in Mitral Stenosis, *Am. Heart J.*, 5, 3: 344 (Feb.), 1930.

Cancer—This paper bears every evidence of being a sound, inclusive, unbiased summary of the present status of our knowledge in regard to the etiology, the treatment, the prevention of cancer.

STALLYBRASS, C. O. Cancer—A Review of Recent Progress, *Pub. Health*, 43, 5: 135 (Feb.), 1930.

Rural Tuberculosis Incidence—Among a group of hospitalized children in Iowa only 16.5 per cent reacted to the intracutaneous tuberculin test. This is an indication how much less general is infection in rural than in urban districts.

TAYLOR, M. H. A Tuberculin Reaction Survey among Hospitalized Children in Iowa, *Am. J. Dis. Child.*, 39, 2: 316 (Feb.), 1930.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Newton, Mass.—The financial statement of the 1928 report of the Board of Health of Newton shows an appropriation of \$49,684, or approximately \$.87 per capita. Of this, \$8,777, or 20.1 per cent of the total expenditure, were for child hygiene; \$10,079 (23.1 per cent) for nursing, and \$9,584 (22.0 per cent) for administration. The excellent diphtheria and scarlet fever records of the past few years are being continued, no deaths from the former having occurred since 1925, or from the latter since 1926. The physical examination of school children has been entirely taken over by the health department. As a result of this work, the percentage of defectives among school children has been reduced from 40 to 12 since 1924. The birth rate has increased from 15.36 to 17.54, and the death rate from 9.75 to 10.6 per 1,000 population.

New York State—Volume II of the 49th annual report of the New York State Department of Health contains the report of the Division of Vital Statistics for the year 1928. The death rate (13.1 per 1,000 population) has been higher only once since 1920. The birth rate of 19.2 was the lowest since complete registration; and the marriage rate, 18.6, the lowest since 1918. However, the infant mortality rate of 65 deaths under 1 year per 1,000 living births was, with the exception of the previous year, the lowest ever recorded. There were 1,295 deaths from puerperal causes, giving a maternal mortality rate of 5.56 per 1,000 births.

The important causes of death are excellently summarized by charts showing the death rates by cause, age and sex for New York City and the rest of the state. Heart disease ranks first as the chief cause of death, 22.2 and 23.5

per cent of all deaths in New York City and the rest of the state, respectively, belonging to this group. Pneumonia ranks second in New York City, with a proportionate mortality of 12.8 per cent, while second place for the rest of the state is accorded to cancer (9.5 per cent of all deaths). Mortalities from typhoid fever (1.8 per 100,000) and from diphtheria (7.4) were the lowest ever recorded with one exception. The death rate from tuberculosis was 82.7, a slight increase over 1927 due to an increase in the rate for New York City, a decrease being shown for the rest of the state. The death rates from diseases of the heart (297.9), cancer (126.7) and diabetes (26.4) were the highest ever recorded. The rate of deaths from automobile accidents (23.0) was higher than in 1927, the increase being due to greater mortality in the rest of the state, the New York City rate having decreased.

An amendment to the Vital Statistics Law enacted in 1929 provides for the payment of actual and necessary expenses to local registrars by their municipalities. The 1929 amendments to the Domestic Relations Law, as affecting the registration of marriages, require the approval of the judge of a children's court to be endorsed upon the marriage license application of girls under 16 years of age, and also require the return of the marriage license and certificate within 5 days after the marriage to the town or city clerk who issued it.

Montreal—The personnel of Montreal's Department of Health has undergone a considerable reorganization and enlargement during the year 1928. The annual report for that year shows an increase in the staff of the Division of Child Hygiene from 11 full-time and 5

part-time inspecting physicians, 1 dentist, and 29 nurses, to 17 full-time physicians, 4 dentists, and 52 nurses. In the Division of Food Inspection, 6 veterinarian inspectors and 6 inspectors of pasteurization have been added, bringing the totals to 9 veterinarian and 7 pasteurization inspectors. The laboratory staff has increased from 3 to 9 members, including the addition of 3 milk bacteriologists.

The efficiency of school medical inspection has been improved by the re-districting of the city into 4 large nursing districts, each of which has been subdivided into 10 subdistricts with a nurse for each. The work of inspecting physicians has likewise been aided by the formation of 16 districts each comprising a baby clinic and supervised by an inspecting physician. During 1928, 68,148 pupils, or 53.24 per cent of those registered in the schools, were examined. Four hundred and fifty per 1,000 of the pupils examined showed one or more defects, excluding dental decay; 523.7 per 1,000 showed one or more dental defects.

A new system of statistical compilation is being organized in order to bring the municipal vital statistics to agreement with that of the Provincial Bureau of Health. For this reason the 1928 general death rate of 14.9 and the infant mortality rate of 143.8 per 1,000 births are not comparable with those of the past.

Arizona—The state of health of Arizona regarding communicable diseases is reported as satisfactory in the 8th biennial report of the State Board of Health for the years 1927–1928. A state milk control program was initiated in 1927 with the aid of the U. S. Public Health Service by the drafting of a Standard Milk Ordinance which was adopted by 17 towns.

Although crippled during 1927 because of the lack of funds, the Sheppard-

Towner program of the Child Hygiene Division gave 46 lectures and talks to 1,252 persons, and 47 health conferences were held with a total of 606 mothers. In 1928, 84 lectures with an attendance of 1,226, and a total of 98 health conferences with 837 mothers attending were given.

J. H. W.

Newark, N. J.—Newark has prepared an attractively bound 352 page report of the Department of Health for 1928. The volume is replete with cuts and graphs depicting the more outstanding phases of the department's work.

Newark's estimated population is 474,000. Its crude death rate is 11.6 per 1,000, which is reduced to a resident rate of 10.9. This is a slight increase over 1927, mainly due to the unusual prevalence of measles and pneumonia, to which was also attributed an increase of 0.5 in the infant mortality rate (63.8). The deaths from measles rose from 3 to 47, while an excess of 153 deaths from pneumonia was shown in 1928 over 1927. The specific death rate for diphtheria has also increased to a record high for the past 15 years; but in no instance was the victim an immunized child. The death rate for tuberculosis has risen slightly. A slight decrease (34) in the number of deaths from heart disease and apoplexy has occurred over 1927.

The physical examination of food handlers was started in 1920. In that year 2,314 examinations were made, which has increased to 16,779 in 1928. The effect of this work is clearly shown in the reduction in the positive tuberculosis found. In 1920, 9 positive cases were found per 1,000 examinations; in 1928 this figure was 0.3. A positive diagnosis was in each case made with the aid of sputum and X-ray findings. Venereal disease incidence among this group was exceptionally low, a percentage of 0.2 for the entire group being found. Only 1 typhoid carrier was

found; no case of diphtheria was ever detected.

The cost of this work was \$9,000 annually; in 1928 the cost per examination was \$.53.

Two Baby-Keep-Well stations were opened in 1928 to bring the total to 16 stations with 26 conferences a week. There were 51,189 visits made by nurses to 4,236 new-born infants, while 16,950 visits were made to the Baby-Keep-Well stations, a score of 5.2 and 1.7 visits per 1,000 births respectively. Midwife attendance has been consistently lowered, 20 per cent of the births being attended by midwives as against 46 per cent in 1918.

Bridgeport, Conn.—The annual health department report of 1928 occupies a portion of the municipal register of 523 pages. On the basis of an estimated population of 182,936, there is recorded a death rate of 9.4. The outstanding educational effort of the year was a cancer control campaign conducted in coöperation with the local medical society.

A symposium for physicians was addressed by 3 leading physicians in the cancer field. A meeting of nurses was addressed by two physicians, while a meeting for teachers was addressed by a foremost authority on cancer. The United Illuminating Company enclosed a leaflet, giving the early symptoms of cancer, in each of their October bills, totaling 50,000. Eight radio talks were given by the health officer, all having been endorsed by the local medical society. Some 5,200 persons attended public lectures, 530 inches of newspaper space were used, and over 66,000 pieces of literature were distributed. As a direct result of the campaign, 302 patients visited their physicians for diagnosis. Of this number, 81 were found to have early signs of cancer, 25 showed a malignant condition still operable, and 26 had cancer in an advanced stage, while

the remainder showed no malignancy. The local medical society, as a result, has requested the Department of Health to establish diagnostic cancer clinics.

New Jersey—The child hygiene nurse appears to be increasing in favor among the communities of New Jersey, for, according to the 52d annual report of the New Jersey State Department of Health for 1929, 18 nurses were paid from local budgets in 1918 as compared with over 100 in 1928, and 55 paid by the state in 1918 as compared with 20 in 1928. The child hygiene nurse assists the community in maintaining the health of the child from the prenatal period to adolescence, including the school period. School nurses have been converted into child hygiene nurses, thus bringing the prenatal and preschool periods within the scope of the nurse's activities, a vital and important part of the correct approach to the child health problem. These nurses have supervised during the past year 5,034 expectant mothers, 18,764 babies, 21,090 preschool children, and 109,988 school children.

The state-wide diphtheria campaign, in which the department has taken an active part for several years, was continued and reports show that in 1928 over 125,000 children in New Jersey were given toxin-antitoxin at public clinics, a number almost equal to the total number of similar treatments in the preceding 7 years.

There were 324 persons desiring to be licensed as health officers, inspectors or as operators of sewage disposal or water treatment plants examined during the year. Only 98, or 30 per cent, of these were able to obtain a mark of 70 or more. The conclusion seems justified that without such tests many unqualified persons might obtain positions demanding specialized training of a high order.

The program of venereal disease con-

trol rests upon two principal activities—a case finding program, and public instruction as to the facts regarding venereal disease. There were 28,000 individuals who attended the 285 talks given throughout the state. Demonstration clinics presenting the newer drugs and methods to physicians were held in four counties during the year.

The legal control of physical connections between public potable water supplies and other unapproved supplies was secured during the year. New cross-connections are prohibited and those in use must be equipped with all bronze double check valves of an approved type, which are allowed only on yearly

permit. Laboratory tests from 76 water supplies of roadside refreshment stands indicated 33, or nearly half, to be contaminated. The increasing importance of such violations of the Sanitary Code is self-evident.

New Jersey was relatively free from serious epidemics of disease during the year ending June 30, 1929. The death rate for the year 1928 was 12.04 per 1,000 population, within half a point of the lowest rate ever attained in the state. The 1928 birth rate (18.95 per 1,000) is the lowest since 1905. The infant mortality rate for 1928 is 65.6 per 1,000 babies born alive, comparing with 61.3 for 1927 and 70.3 for 1926.

NEWS FROM THE FIELD

MICHIGAN PUBLIC HEALTH ASSOCIATION

THE Ninth Annual Conference of the Michigan Public Health Association in coöperation with the Michigan Department of Health was held on January 8, 9, and 10 in Lansing, Mich. The following officers were elected: President, Don M. Griswold, M.D.; Vice President, Carrie Webster; Secretary-Treasurer, W. J. V. Deacon, M.D.; and Representative on Governing Council of the A. P. H. A., Guy L. Kiefer, M.D.

YALE SCHOOL OF MEDICINE

THE General Education Board of New York has made a gift of \$400,000 to the Yale School of Medicine. The announcement of the gift was made by Dean Milton C. Winternitz of the School of Medicine. This supplements a \$2,000,000 gift from the same board and Rockefeller Foundation a year ago. The money is to be used for further development on the site of the Sterling Hall of Medicine, and also for other buildings.

TEXAS WATER WORKS SHORT SCHOOL

THE Twelfth Texas Water Works Short School was held January 27-30, with a total of 272 registrants. The attendance at the laboratory sessions for the first two days broke all previous records with almost 100 present.

John R. Baylis of Chicago presented discussions on two subjects: "The Developments in the Treatment of Highly Polluted Water in the Removal of Bad Tastes and Odors," and "Conclusions at the Chicago Filtration Plant."

Waco, Tex., was selected as the next annual meeting place. The following officers were elected: President, L. A.

Grimes; First Vice-President, W. H. Deaton; Second Vice-President, Bud A. Randolph; Third Vice-President, J. R. John; Fourth Vice-President, George Mincy; Secretary, V. M. Ehlers; Treasurer, E. G. Eggert, and Editor, Ella G. White.

Among the resolutions passed is the following:

WHEREAS, the American Public Health Association is to hold its Annual Meeting in Fort Worth, Tex., the latter part of next October, and

WHEREAS, this organization includes in its membership a section for laboratory workers and a section for public health engineers; therefore, be it

RESOLVED, first, that we give the various Fort Worth local committees our support in making a success of this meeting; second, that the secretary be instructed to prepare a chart or exhibit which will be representative of our organization and will indicate the activities and objectives of our organization.

DR. PARRAN, NEW YORK COMMISSIONER OF HEALTH

THOMAS J. Parran, Jr., M.D., has been named Commissioner of Health of New York State by Governor Roosevelt. Dr. Parran took office on March 1. He has been Assistant Surgeon General of the U. S. Public Health Service and is widely known in the public health field.

METROPOLITAN AREA FOOD AND HEALTH OFFICIALS FORM NEW ASSOCIATION

JUDGE B. A. Pyrke, New York State Commissioner of Agriculture and Markets, was elected president of a new association of federal, state, county and city food and health officials of the metropolitan area formed March 5 in New York City.

Forty food and health officials attended the meeting representing the federal government, the states New York, New Jersey and Connecticut, and the following cities: New York, Albany, Port Chester, Yonkers, Riverhead, Newark, Montclair, Trenton, Hackensack, Orange, East Orange, Jersey City, Asbury Park, Plainfield, Elizabeth, Paterson, New Haven, and Greenwich.

The purpose of the organization is to bring together officials concerned with food and public health work so they may discuss common problems, exchange notes, and coördinate and correlate activities to enforce more effectively their various laws and ordinances.

The first meeting of the organization was opened under the temporary chairmanship of W. S. Frisbie, in charge of coöperation, Food, Drug and Insecticide Administration, U. S. Department of Agriculture, Washington, D. C. Problems relating to canned foods, poultry and milk were considered and discussed. Other officers elected were W. R. M. Wharton, Chief of Eastern District, Food, Drug and Insecticide Administration, as vice-president, and Joseph Calloway, Chief of New York Station, F. D. I. Administration, as secretary.

The next meeting will be held on the first Wednesday in June. The group expressed a desire to have arranged for them at that time a display of various types of illegal poultry which have in the past been found on the market.

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

THE annual meeting of the Southern California Public Health Association was held on February 14 in San Francisco. The following officers were elected: President, Dr. George Parrish; President-elect, Dr. Sven Lokrantz; 1st Vice President, Dr. W. B. Wells; 2d Vice President, Dr. A. M. Lesem; Secretary-Treasurer, Dr. Giles S. Porter; and Head of Executive Committee, Dr. J. L. Pomeroy.

A resolution was passed recommending that papers presented at sectional meetings be made available through the A. P. H. A. to members of all affiliated health associations, supporting the resolutions of the West Virginia Public Health Association (*A. J. P. H.*, 20, 2: 238 (Feb.), 1930).

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

THE Annual Meeting of the Northern California Public Health Association was held on the campus of Leland Stanford University, Palo Alto, on January 11.

The officers elected for the coming year are: President, Dr. Adelaide Brown; Vice Presidents, Dr. Guy Millberry, Dr. Thomas A. Storey, and Dr. Karl F. Meyer; Secretary, Dr. Walter H. Brown; and Treasurer, Mary E. Davis, R.N.

The Association officially approved the request of the West Virginia Public Health Association that the A. P. H. A. work out a method whereby the papers in the local Associations might be published and made available for the various workers in the public health field.

UTICA'S MOST USEFUL CITIZEN FOR 1929

CONCLUDING that without health the community and its citizens cannot prosper, the Board of Awards of the Utica (N. Y.) *Observer-Dispatch* decided that any outstanding contribution to the health of Utica deserves first consideration and highest recognition. Therefore Walter G. Hollingsworth, M.D., Fellow, A. P. H. A., was selected as Utica's most useful citizen for 1929 because of his work in the Division of Food and Hygiene.

MILK AND CREAM CONTESTS

THE U. S. Bureau of Dairy Industry has prepared a department circular, *How to Conduct Milk and Cream Contests* (Circular 384-C), of which a revised edition is now available for dis-

tribution. This circular offers simple and definite suggestions for conducting such contests and explains the approved methods of scoring. It includes a model score card and several tables which show how to make deductions from a perfect score. The recommended score card allows a maximum of 45 points out of 100 for low bacterial count, 25 points for flavor and odor, 10 points for sediment, 15 points for temperature or acidity, and 5 points for the condition of the bottle and cap. Apply to Office of Information, U. S. Department of Agriculture, Washington, D. C.

MEXICANS AND PUBLIC HEALTH

SEÑOR Alfonso Isunza, of Vera Cruz, has been visiting Texas making an intensive study and inspection tour of the various sanitary projects and improvements, including water supplies, sewage disposal, milk sanitation, chlorination, and mosquito control, under the direction of the Texas State Health Officer and the Sanitary Engineering Staff. This study is along the same lines as one made last summer by Señor Anastasio Guzman of the engineering staff of the University of Mexico. These gentlemen with some ten or more other prominent engineers in the Republic of Mexico have indicated their

intention of attending the 59th Annual Meeting of the American Public Health Association.

NEW JERSEY NURSES TO MEET

THE annual state conference of the New Jersey Nurses will be held in Elizabeth, N. J., from April 10 to 12. Some of the organizations meeting will be the League of Nursing Education, New Jersey State Nurses Association, New Jersey State Association for Public Health Nursing and the Northern New Jersey Federation of Visiting Nurse Associations.

MENTAL HYGIENE SPEAKERS

THE International Congress for Mental Hygiene, May 5-10, 1930, is to be attended by many foreign delegates. Some of these will be available for lecture engagements. Their interests cover a very wide range, and it is probable that a suitable speaker could be found for most any group interested in human behavior. The National Committee for Mental Hygiene will provide information about these visitors, their subjects, their possible itinerary, and availability to any organization interest. Apply to Dr. George S. Stevenson, 370 Seventh Avenue, New York, N. Y.

PERSONALS

DR. JAMES J. DURRETT, Chief of Drug Control, U. S. Department of Agriculture, was elected February 12, 1930, by the State Committee of Public Health of Alabama to be State Health Officer to succeed Dr. Stuart Graves, Dean of the School of Medicine of the University of Alabama, who was loaned by the University to be State Health Officer pro tempore.

DR. ARTHUR W. K. AKERLEY, for many years a member of the A. P. H. A., died at his home on Flathead Lake, Somers, Mont., on January 30, 1930, at the age of 62 years.

ALICE DUFF, formerly with the Preston County Health Unit, is now a member of the new Monongahela County Health Unit, Morgantown, W. Va.

NELSON E. CLEMENS, D.V.M., has been appointed Health Officer of Hayward,

Calif., to succeed Dr. Fred William Browning, who died recently.

STEPHEN MALONEY, Secretary of the Massachusetts Association of Boards of Health, died suddenly in January of this year.

DR. WILLIAM H. CULLEN, Health Officer of Brasher Falls, N. Y., died on January 28 of pneumonia.

JAMES LOUCHEIM, registrar of vital statistics for Lawrence, N. Y., since 1918, has been reappointed for a period of 4 years. He is believed to be

the oldest registrar in the state—he is now 84 years old.

DR. C. FLOYD HAVILAND, superintendent of the Manhattan State Hospital and former State Hospital Commissioner, died in Cairo, Egypt, in January.

FRANCIS E. FRONCZAK, M.D., Health Commissioner of Buffalo, N. Y., was unanimously elected a Fellow of the Royal Institute of Public Health by the Institute at a meeting held in London, England, recently.

CONFERENCES

Apr. 3-5, Progressive Education Association, Washington, D. C.

Apr. 7-10, Florida State Conference of Social Work, Jacksonville, Fla.

Apr. 8-11, Short Course on Water Purification and Sewage Treatment, University of Florida, Gainesville, Fla.

Apr. 9-11, Iowa Water Works Operators School, Iowa City, Ia.

Apr. 10-12, New Jersey State Nurses Convention, Elizabeth, N. J.

Apr. 22-23, Arizona Public Health Association, Phoenix, Ariz.

May 5, Texas Health Officers' Conference, Mineral Wells, Tex.

May 5-10, First International Congress on Mental Hygiene, Washington, D.C.

May 6-8, Annual Meeting, State Medical Association of Texas, Mineral Wells, Tex.

June 2, week of, American Water Works Association, St. Louis, Mo.

June 6-14, National Conference of Social Work, Boston, Mass.

June 12-14, Western Branch of American Public Health Association, Salt Lake City, Utah

June 18-19, State and Provincial Health Authorities of North America, Washington, D. C.

June 20-21, Conference of the Surgeon General, Washington, D. C.

FOREIGN

May 19-21, Second International Malaria Congress, Algiers, Algeria

June 4-9, Congress of Royal Institute of Public Health, Portsmouth, England

June 21-28, Royal Sanitary Institute, 41st Congress and Health Exhibition, Margate, England

Aug. 3-9, Second International Congress for Sex Research, London, England

Aug. 4-9, International Veterinary Congress, London, England

Pre-disaster Preparedness^{*}

CONSIDERING the various public health phases of disaster relief it can best be handled by sub-division into three sections: Pre-disaster Preparedness, Emergency Relief, and Post-disaster Relief (rehabilitation). The committee proposes to consider each as a unit and presents herewith pre-disaster preparedness as relates to the public health engineering aspect of disaster relief.

Disasters affecting cities, towns or rural areas can be classified as to causes:

1. Floods, overflows, water damage, tidal waves
2. Fires, conflagrations, forest
3. Wind, tornado, hurricane, coastal gales
4. Explosions, munitions, factories, mines, institutions
5. Drought, water supply failures
6. Disease outbreaks
7. Earthquakes

Any or several of these types of disaster may bring up problems where the mature judgment of the engineer may be of utmost importance in arriving at a prompt, effective solution.

Disasters are no longer minor or chance occurrences, but each year they are more widespread, more devastating, more demanding of the harmonious assistance of such agencies as:

1. Official, Governmental Agencies:
 - Federal, State, County and City Health Departments
 - State Militia or Police organizations
 - U. S. Army, Navy and Coast Guards
 - Agricultural, Mining, Forestry Departments
2. Official Relief Agencies:
 - National or local American Red Cross
3. Unofficial Agencies:
 - American Legion
 - Salvation Army
 - Religious and Fraternal Orders

^{*} Report of the Committee on Disaster Relief, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

The problem of harmonizing forces prior to disaster is worthy of our best efforts, and it is hoped that this report may stimulate some thought, if not action.

STATE DISASTER BOARD PLAN

Primarily any relief work is governed by the finances available, and it is recommended that for states where disasters are of common occurrence there be available through legislative appropriations an emergency fund of at least \$50,000, at the disposal of the governor, to be used only in disasters of magnitude such as floods, conflagrations, hurricanes, disease outbreaks, etc., as determined by law. Such a fund should be dispensed only through state employees, and a State Disaster Board is suggested to consist of:

The Governor as Chairman
Adjutant General
State Comptroller
State Highway Commissioner
State Health Officer
Public Service Commissioner or Utility Representative
State Commissioner of Welfare
American National Red Cross representative appointed by Washington Headquarters

Partial allocations of funds, equipment, and duties, could be made in advance for emergency work and thrown into operation by direction of the governor. After a preliminary field check of losses and conditions, a meeting of such board could allot specific items, plan procedure, and get under way with very little lost motion. Pre-disaster preparedness would indicate authorized characters and methods of expenditures of funds.

1. In presenting a State Disaster Board plan it is appreciated that local conditions will indicate the structure of such a board, and that such a board is not an organization to function all the time, but merely a board of known components called into service at the will of the governor, who as chief executive should head the board.

2. The Adjutant General directing the National Guard or Militia should be a member, to determine the use and function of militia units. In disasters of great magnitude, involving several cities or counties, militia units from nearby points should be called in to assist local civil authorities in the protection of property, regulation of traffic, preservation of order, and similar police matters. The use of National Guard property such as tents, camping equipment, medical and other supplies, radio transmission outfits, etc., may be necessary and can best be administered by Guard personnel. If necessary, any area may be placed under military control and administered under martial law, but such action is not recommended.

3. The state comptroller should designate the manner in which emergency financial matters are to be handled.

4. The state highway commissioner might be instrumental in securing transportation and crews of laborers from other parts of the state so that roads may be reopened, bridges and automobile traffic restored. State trucks can well be used for emergency work, handling supplies, equipment and perhaps the dead.

5. The state health officer should be a member of the board because of the increased possibilities of spread of communicable disease under conditions created by disasters, and the importance that the press and general public attach to the aftermath of a disaster with its sudden change in the ordered life of thousands of people. He should be the executive head of all health matters, acting, however, only in coöperation with established local health agencies, or where such an agency does not exist or is incapable of proper functioning.

6. The state public service commissioner or representative of the power, communication, or transportation utilities, should be on the board to determine the action of such utilities. Such a representative should be acceptable to the interests and they should agree to obey his orders in disaster time.

7. The State Welfare Commissioner may in some instances exercise board powers as to housing, and his assistance may be of great value in the rehabilitation program including, as it may, use of convict labor, placing of orphans in institutions, etc.

8. A representative of the American National Red Cross appointed by Washington should be on the Board to make plain the limits of Red Cross participation in the relief program and to establish harmonious relations. This is especially desirable if disaster strikes in a community which has no official governmental or Red Cross organization.

Such a board can be extended to cope with any disaster, depending upon the local conditions of government. The plan is advanced to provide for instant and effective action in an emergency and to correlate the work of state agencies with that of the American National Red Cross. Though the American National Red Cross is the official disaster relief agency, chartered by the federal government, among other things—

. . . to continue and carry on a system of national and international relief in times of peace and to apply the same in investigating the suffering caused by pestilence, famine, fire, floods and other great national calamities and to devise and carry on measures for preventing the same . . .

nevertheless there are certain things which we might expect, which it will not do, even though it would materially aid in establishing conditions greatly affecting the morale, health and welfare of the stricken people. In the field of public health the policies are rapidly becoming reorganized under William DeKleine, M.D., Director of Medical Service, an official experienced in the problems confronting the public health officer.

The foregoing is intended to provide the background for the work of the public health engineers. Considering the state as a unit, the engineer of the state health department is usually the keyman for immediate field action necessary to protect the public health. He therefore should be charged with the pre-disaster organization of all engineering and sanitary personnel and procedure.

THE PROBLEMS

The problems involving engineering activities in the mentioned types of disasters are:

- Provision of emergency housing accommodations
- Provision of necessities of life, such as, water, food, including milk and ice and waste disposal
- Handling of refugees—creation of good morale
- Disposal of dead—human and animal
- Rehabilitation of families

In each, the engineer has a vital part. For emergency housing the availability of such structures as schoolhouses, especially those equipped with cafeteria facilities, churches, parish or Sunday school rooms, gymnasiums, etc., armories, warehouses, ball parks, race tracks, fair grounds, auto tourist camps, etc., should be known. These could be used temporarily for refugee or labor camps. No place should be considered unless safe drinking water under adequate pressure is available or can easily be made so. Tent camps for refugees are not desirable and unless absolutely necessary should not be used. The engineer should be able to establish, or tell those who desire to establish a camp where it can best be located, where safety from inundation is assured, good drainage available, safe water supply under pressure can be had. The transportation of foodstuffs into the camp must be considered. Good excreta disposal is essential and should be provided at the earliest possible moment. Pit privies must be furnished in the absence of sewerage. Shower baths should be installed promptly.

Dr. DeKleine says:

The organization of refugee camps, emergency hospitals and the like are, I believe, functions of the Red Cross although . . . the selection of the site and sanitary regulations should meet the requirements of the local and state health departments. Their advice should be sought wherever possible.

Provision must always be made to protect the refugees or laborers in camps from insects pests whether they transmit disease or not.

Water service should be restored at once and the engineer should be able to assure the public at the earliest possible moment that the

supply is available and safe. Great care should be exercised in condemning a supply or advocating the boiling of water for drinking purposes. The harm done to the morale of the people and the danger of their using water more unsafe than the public supply should be weighed against its chance pollution. The engineer should arrange beforehand for running transmission lines to the water works, thence to the hospitals, milk plants, emergency housing structures, etc. Standby gasoline engine or electric generating equipment should be part of every water works, but if not available, fire engines can be used if emergency couplings are available. Plans for chlorination should be made, but care taken not to create tastes or odors which would lead people unaccustomed to chlorinated water to seek other sources of supply.

In rural sections the use of chemical sterilization is recommended and full utilization of bottled water supplies in the area should be planned. Chlorination should be done at the plants. Water can often be shipped into the area in tank cars, and provision should be made in advance with the railroad officials (water supply department) for the prompt handling of such shipments from approved sources. These should be chlorinated in the car at the source.

For staple food supplies the engineer need have little worry as they will be forthcoming. In time of disaster milk preferably should be canned or dried. The engineer should know the character and capacities of available pasteurization equipment, for medical officers, or the local authorities, may order all milk pasteurized when the local plants can handle only one-tenth of it. Preliminary agreements with the railroads should be made to have express service given to shipments of water, milk, ice, perishable foodstuffs and urgent supplies. Special marking tags might be developed to expedite shipments.

Waste disposal can rarely be planned in advance but ordinarily pit privies can be planned for, or the restoration of plumbing service. If the plumbers can be approached in advance there is a possibility of securing a detail from a nearby town to make temporary repairs.

Creation of good morale among the citizenry, and handling of refugees, are problems that the engineer has little to do with, but he can be of great assistance in explaining to excited councilmen, committees, etc., the simple facts of disease transmission. The engineer has to meet all conditions arising, always bearing in mind that optimism is worth a lot in times of disaster. In disasters of large magnitude the engineer may be called upon to assist in gathering and disposing of the dead. His knowledge of soil and topographical conditions may indicate to him what method of procedure—burial or cremation

—is possible. Animal bodies can best be disposed of by incineration, using wood débris and oil. Burial may be used if topographical conditions permit.

PERSONNEL

The engineer should know definitely where persons are who might be listed as available when needed; how long they can be kept on duty; and how their services may be obtained. Among the needed personnel may be listed:

1. Trained Public Health Engineers and Sanitary Inspectors:
 - State, county, city, or district departments
 - Federal, U. S. Public Health Service
 - On staff of large utilities or manufacturing plants
2. Plant Operators:
 - Water plant employees, filter men, chemists, pump men, etc.
 - Milk plant pasteurization operators, etc.
 - Sewage treatment plant operators

In the time of disaster, assistance can be called for from men who are in some measure in touch with the local conditions; who appreciate the natural conditions of the area, who know how to handle very similar problems. Thus for a disaster affecting one area, the first call for personnel should be made upon men within that state or nearby states. Full utilization of local (state) personnel should be made before outside assistance is sought.

The engineer should have available a list of those who can be mobilized and to whom the request for such assistance should be sent. It is also of vital importance to know just how long such assistance should or can be kept without incurring financial obligations. Often men will be freely loaned by their employers for the emergency, but after the glamour of relief work disappears and routine is established that "going home" call must be met. Definite understanding must be had as to the duration of service of drafted personnel, and in every case it should be definitely understood that no man is to leave his post until relieved by orders from the official in charge. Otherwise a trained water works operator may be detailed on a plant and left in charge, and perhaps two days later one may find him gone and the plant running by itself. Preliminary understanding is the only way to handle volunteer service.

Necessary labor should be carried on a regular pay roll and no dependence placed upon volunteers of the laboring class. Twenty-five paid laborers are worth more than 250 volunteers, and provisions should be made for prompt hiring and paying of such men from the state funds. This turns loose the money so needed in a devastated

area. A few dollars in the pockets of a man who has lost all is a tremendous factor in restoring courage and morale.

Here it might be wise to mention the policy of the Wallace and Tiernan Company with regard to disaster relief work. Every field representative of this company is directed to report in person to the chief engineer of the state board of health having jurisdiction, equipped with such supplies and materials as are available, and to place himself and equipment at the orders of the chief engineer. Such a policy is to be commended.

SUPPLIES AND EQUIPMENT

In the matter of supplies and equipment, each engineer will have to consider what are needed, where they can be obtained most quickly and who will pay for them. Such supplies are:

1. Chlorine control apparatus, gas and orthotolidine for water and sewage sterilization
2. Hypochlorite and similar materials for household, field or small plant use
3. Automobile and railroad tanks for transporting water and location of acceptable supplies
4. Gasoline engines, portable electric pumps and generators for pumping water
5. Water storage tanks, 5-gallon glass bottles, milk cans, field workers' canteens
6. Outboard motors, trucks capable of negotiating flooded roads
7. Disinfectants, hydrated lime, cleaning compounds, commercial preparations, deodorants, oils for mosquito work, etc.
8. Insect repellents, sprays, etc.
9. Tents, barracks, armories, race tracks, warehouses
10. Camping equipment, cooking and eating utensils, wire screens, blankets, mosquito nets
11. Milk plant supplies, thermometers, etc.
12. Fuel, oils, gasoline, canned heat for field use
13. Incidentals, flash lights, raincoats, high boots
14. Disaster data

Each engineer should study his area carefully and check it at least yearly. A small supply of materials might well be kept on hand especially for the sterilization of water. It is also thought advisable to have a supply of what may be called "disaster data booklets," devoted to the type of disaster prevalent in each state, to be distributed among the population affected, telling in simple language the facts of disease prevention in time of disaster and assuring the people in no uncertain terms that odors, from dead animals, for example, will not "breed disease," that cholera will not break out suddenly because of the overflow of land, etc. Some statements as to disinfectants, their use or

abuse, would be welcome. Public health workers are often too fearful of results, whereas in times of disaster the morale of the public must be restored and their fears allayed. If one is hesitant about statements the public soon loses faith in him. Directions must be simple and easily understood, and capable of being carried out under disaster conditions. Outboard motors, resuscitation apparatus, oxygen hoods, pulmotors, gas masks and such equipment should be available to some state agency, or the knowledge of where it can be obtained known to the engineer.

The engineer in disaster relief must be one of the workers as well as an executive; he must know the people who will be found on the job at such times. He should prepare for disaster by having many close friends who are in key positions with utilities, relief organization officials, etc. He should be an active member of such organizations as the American National Red Cross, and American Legion. Membership in the clubs such as Rotary, Kiwanis, etc., is invaluable, for through such organizations desirable contact is established throughout the state. Fraternal organizations are also of value. The wider his acquaintanceship, and knowledge of his state or city, the better it is for him in time of disaster. Friendship is the best shear for cutting red tape and getting to the right person. Advance information as to courses of storms, height and approximate time of overflow, etc., can often be secured from:

1. Official Governmental Bureaus, Weather, Forestry, Mining, War and Navy Departments, Engineering Offices
2. Public Relations Officers of Railroads, Utilities, Telephone Companies, Radio Companies, etc.

Governmental airplanes can sometimes be had to make a rapid reconnaissance and preliminary estimate of the situation. Maps of all descriptions, including railway right-of-ways, maps of levees and drainage districts, etc., are of value in locating high areas for camp sites.

PREPAREDNESS

In every state there are communities having American Red Cross chapters. These chapters are given charters defining the territorial limits within which they can operate. In some states there are large areas in which there is no Red Cross organization or territorial responsibility. It is suggested that some plan could be devised by subdividing the state into districts, and assigning to the local chapters the responsibility for carrying relief in event of disaster within their area rather than limiting their action to charter definitions. In this way rural disasters could be more easily handled. Each Red Cross chapter

should have a local Disaster Preparedness and Relief committee (see A. R. C. No. 209—*When Disaster Strikes*); with sub-committees covering food, clothing, housing, transportation, medical aid, etc.

The engineer should know the functions of these committees and their availability—they are valuable aids to him in any preparedness work and he should use them.

Local health departments should be organized for disaster relief work and their organization may be patterned after that of the state health department. Especially should the local health department have its staff working in harmony with all relief agencies and the time to establish cordial relations is before disaster strikes.

The need for state health departments to be prepared for disaster duties is becoming more apparent every year. The public health problems that follow in the wake of every storm and flood are often staggering, and unless health departments are prepared serious difficulties may be expected. The midwestern tornado of 1925, the Mississippi flood of 1927, and Florida's hurricanes of 1926 and 1928, are illustrations. Each state health department should be organized to handle its own emergency problems. Outside agencies may offer assistance when health departments are not able to cope with the problems; but each health department must realize that public health supervision is its responsibility.

Disaster preparedness should be considered as a public health necessity by every state health department, as well as an opportunity to render better service. The State and Provincial Health Officers and the American Red Cross have given this subject much study. It is therefore recommended that this Association take some definite steps to develop a program with the various official agencies.

The engineer is but a part of a health organization though fortunately he is alert to the call of danger and never fails to answer. He has an opportunity to blaze the way by organizing his own department on a disaster relief program and then selling his ideas to his chief. The problem is not a small one—it is worthy of the best of us. It is an amazing opportunity for real constructive service. As engineers we have a definite part in the program, and we offer our coöperation and services to similar committees of other organizations such as the American Red Cross, which has no engineering personnel.

AMERICAN NATIONAL RED CROSS POLICY

What can be expected of the American National Red Cross in matters of interest to the engineer? Dr. DeKleine stated before the State and Provincial Health Authorities of North America:

The Red Cross deems it important that every sound and practical public health measure which will contribute to the immediate health and well being of the people of the disaster stricken area shall be utilized to the fullest extent. It is willing to assist local health agencies in this effort and contribute the additional personnel, supplies and facilities which they lack or cannot otherwise secure. . . .

Financial and other assistance will be given when the official health agencies are not able to cope with the problem, for reasons already mentioned, and when it is clearly indicated that such assistance is needed and wanted. Where health departments do not have and cannot otherwise secure sufficient funds or personnel the Red Cross will purchase or otherwise provide the supplies and facilities necessary, and help secure the additional personnel.

The Red Cross will make every effort to maintain a friendly and coöperative relationship with all the medical and health agencies and endeavor to coördinate all the health activities in the disaster area.

Antivivisection

THERE are many "Anti"-bodies, apart from those which save us from disease. Some of them are good, most of them are bad. I cannot bring myself to object to anti-aircraft guns, and there is probably much to say for the anti-Saloon league. Anti-dazzle, anti-fire, anti-germ, anti-vibration, anti-waste, and anti-slavery (to quote the telephone directory), all sound beneficent enough. In anti-prohibition, however, anti-socialist, anti-communist and anti-vaccination we begin to tread on the dangerous ground of propaganda; while in London the anti-mind is revealed, in its highest form, in four separate and independent anti-vivisection societies, all fighting against one another in the same great cause. This anti-mind is no new phenomenon. In my recent researches I came upon an Anti-Rail-Road Journal dated 1835. The Editor claims, as Dr. Hadwen would, that he is "fighting only on the side of truth," "on behalf of some of the most valuable, but least defended interests." This journal contains "an exposure of the Railway System," and it is interesting to record that the list of those who subscribed to a pamphlet "Rail-Road Impositions Detected" is headed by the Provost and Fellows of Eton College, followed by fifteen canal companies, three steam waggon companies, several public houses, and a representative of Messrs. Pickford, carriers. The high ideals professed, and the flowery language employed, by the anti-rail-road enthusiasts of 1835 are so similar to those of anti-vivisection to-day that there are grounds for the hope that the future of both may be the same. . . . I admit—to its credit—that the Anti-Rail-Road Journal avoided calling upon the Almighty to bear witness to the purity of its motives; the Anti-Vivisectionists have not the same compunction.—From "Enemies of Knowledge," by Professor A. V. Hill, *The Quarterly Journal of the Research Defence Society*, Summer, 1929, p. 8.

Public Health and Medical Problems in Disasters*

WILLIAM DEKLEINE, M. D., F. A. P. H. A.

Director, Medical Service, American National Red Cross, Washington, D. C.

THE American Red Cross is a disaster relief agency chartered as such by the federal government. The Congressional Charter, under which it operates, charges it, among other things, with the duty —“to continue and carry on a system of national and international relief in time of peace and to apply the same in mitigating the sufferings caused by pestilence, famine, fire, floods and other national calamities, and to devise and carry on measures for preventing the same.”

Funds for maintaining the Red Cross organization are, however, not obtained through governmental sources, but entirely through voluntary subscriptions. It is therefore a semi-official agency. Its duties in disasters are official, but the financial support for all its activities is voluntary.

The Red Cross functions in the field principally through the medium of local chapters, of which there are about 3,500 in the continental United States, 10 in our insular possessions and neighboring islands. Where chapters are prepared for disaster duty, they generally assume the leadership in the emergency relief work. Chapter preparedness is one of the objectives of the national organization. Such communities, therefore, conduct their own relief work at least until it is determined that outside assistance is necessary. The national organization participates in the relief program only where communities are not able to cope with the situation, or where assistance is urgently needed or requested.

Red Cross relief in disasters is not based on the loss sustained by individuals or families, but on actual need only. Relief is intended primarily for the emergency needs of those who are in distress—to feed, clothe, and shelter them temporarily; to safeguard their health; to provide medical, nursing and hospital care; to assist them in rebuilding their homes and to help restore normal living conditions. Those individuals and families who are able to cope with the situation without material assistance are expected to do so.

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

There is, however, an emergency period during which it is difficult and often impossible to distinguish the one from the other. The situation is often so very critical that assistance must be given to every one who appears to be in need. That applies to medical as well as to other forms of relief. The necessities with which to sustain life and health must be provided promptly for all, and must be continued until the critical period has passed. There is no time to investigate.

Every effort is made to organize the relief work as early as possible on the basis of actual need. All families and individuals who are receiving help, or may need it, are registered; their circumstances are carefully investigated; and relief continued only for those who deserve it. Rebuilding the homes and other rehabilitation problems are matters that require careful investigation and study before awards are granted for that purpose. In Red Cross language, this phase of relief work is designated as the rehabilitation period.

The emergency period may last only a few days, or continue for several weeks. Refugee camps are generally necessary in large disasters. They are hurriedly set up in buildings or in army tents. Food must be provided through community kitchens and canteen service. Those seriously ill and injured are taken to hospitals in the community, or in neighboring cities. Medical and nursing service, emergency medical stations and increased hospital accommodations must frequently be provided, and measures instituted for the protection of the public health. These are emergency needs and must be provided promptly.

The public health and medical problems are not limited to the emergency period. Many of them extend over considerable time and new ones may develop several weeks after the disaster. There may be a sudden increase in illness among the disaster population. Pneumonia and other respiratory infections are not uncommon. Typhoid fever caused by contaminated water, scarlet fever, measles, and small-pox resulting from overcrowding, may occur in epidemic form. Dysentery, particularly in tropical climates, and malaria may increase. Special maternity service must sometimes be provided particularly where the disaster involves a large number of families as in the Mississippi flood. These problems frequently hinder the progress of the rehabilitation program and must be solved before normal living conditions can be restored.

There are two major health problems in nearly every large disaster—safeguarding the health of the disaster area, and providing medical care for the sick and injured. From an administrative point of view these are distinctly separate problems and must be so regarded in

organizing the relief work. The first is the duty of the constituted health authorities; the second is the function of the local medical profession and hospitals.

The Red Cross does not sponsor or direct the health activities in a disaster area; neither does it assume the responsibility for the care of disaster patients. These are clearly the duty and function of local agencies. If, however, communities have not adequate health service, or if the medical, nursing and hospital facilities are inadequate, it is the duty of the relief agency to assist them. There is no attempt to supersede local agencies. The Red Cross can render the best public health and medical service in disasters, we believe, not by sponsoring these duties, but by providing for the local health authorities and medical profession the supplies, facilities and personnel which they lack and need for the emergency.

It is important that every sound and practical public health measure which will contribute to the immediate health and welfare of the people in the stricken area is utilized to the fullest extent. The sudden change from normal life in the home to crowded and often unsanitary conditions in refugee camps and other places of shelter; the contamination of water supplies, particularly in floods; the increased area of stagnant water in districts already infested with malaria; diarrheal diseases, especially in tropical climates; and other problems demand serious effort on the part of public health officials. Much unnecessary illness can be prevented if prompt action is taken and if the public health work is organized and conducted on the basis of sound public health policy and procedure. Incidentally, a disaster affords an excellent opportunity to educate the public to the advantages of adequate public health protection.

The Red Cross endeavors to coöperate in every way possible with the local medical profession and to assist them in the difficult problems which confront them. It aims to provide for them what they lack and need for the emergency. In organizing the medical relief work, every effort is made to maintain and restore a normal relationship between physicians and patients. Preference is always given to local physicians when it is necessary to employ them for duty at emergency stations, refugee centers, or to assist health departments at immunization clinics.

Where disasters cover a large territory, additional medical and public health personnel are frequently required, to assist in the administrative duties, and to help make a survey of the critical needs of the area. Representatives of the U. S. Public Health Service, the Medical Service of the Army, and physicians with previous disaster

experience often assist in these duties. It should be understood, however, that they are used primarily for the purposes indicated and not for giving medical care to disaster patients, or for local public health duty.

The direction and supervision of the nurses employed by the Red Cross for disaster duty cannot be delegated to any other agency. Because of the large numbers frequently employed, and because of the nature of their work, it is necessary that they be directed by the Red Cross Nursing Service. Through direct contacts with the home, they are frequently able to obtain information most valuable in determining the real need of many families. It is therefore important that a very close liaison be maintained between the Nursing Service and other Red Cross divisions. This is not possible unless they are directed and supervised by the same agency.

The public health and medical activities in which the Red Cross is most frequently called upon to assist or participate may be summarized as follows:

1. Providing additional personnel—physicians, public health nurses, sanitary engineers and sanitary officers—to assist health departments and to staff emergency medical stations, emergency hospitals, and refugee centers. The nurses provided by the Red Cross generally serve the dual purpose of assisting in public health nursing and in bedside care of disaster patients in the homes and hospitals.

2. Sanitation of the disaster area—This includes examination of the public and private water supplies, the adoption of measures to insure safe drinking water and food supplies, the disposal of dead bodies and other sanitation problems.

3. The control of communicable diseases—This includes the usual measures such as isolation in the home, hospitalization and immunization. The immunization of susceptible individuals against typhoid and smallpox is generally an important public health activity in disasters.

4. Providing additional hospital facilities—This is accomplished either by expanding existing hospitals, or by establishing independent emergency hospitals in suitable quarters. The latter are set up only where there are no local hospitals or where expansion is not possible or desirable. Tent hospitals are used only as a last resort. Provision must sometimes be made for the care of maternity cases.

5. Establishing emergency medical stations and dispensaries at refugee centers and other convenient places where disaster patients may apply for medical care.

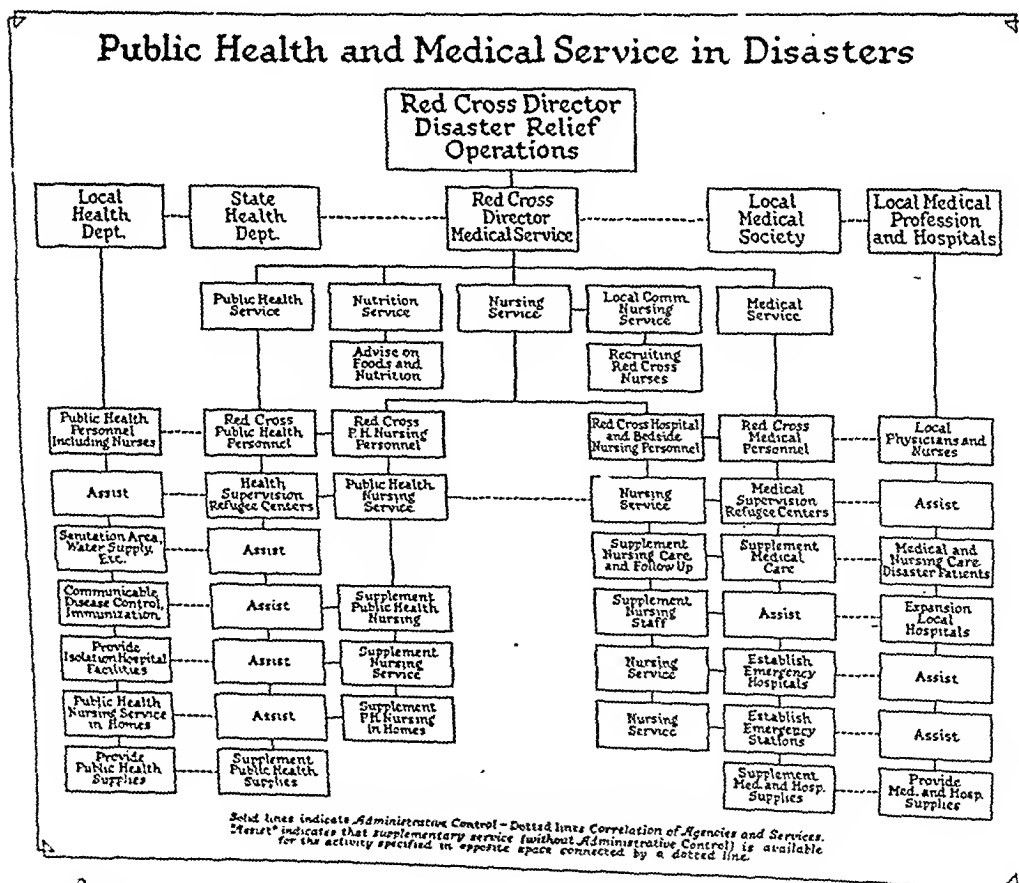

6. Providing public health and medical supplies for use by the health agencies, physicians and nurses. Smallpox and typhoid vaccines, tetanus and diphtheria antitoxin, bandages, surgical dressings and a variety of medical and surgical supplies are generally necessary.

7. Medical and nursing supervision of refugee centers—The care of individuals temporarily housed in refugee centers is a definite responsibility of the Red Cross.

Refugee camps, emergency stations, and emergency hospitals directed by the Red Cross are, for all intents and purposes, Red Cross families or centers. That is especially true of refugee camps. The

This should not be interpreted to mean that local physicians and official health agencies do not have access to these centers and have no responsibility toward individuals temporarily under Red Cross care and supervision. Physicians are expected to maintain the same relationship with disaster patients in camp and in emergency hospitals as with those outside. The public health officials must exercise the same authority and relation toward Red Cross centers of this character that they do, in normal times, toward other institutions or families where a large number of people are housed. The enforcement of laws and regulations governing the control of communicable diseases, the immunization of individuals in camp as well as those outside, and similar duties must be assumed by the official health agencies.

The Red Cross must, however, assume certain definite responsibilities for the health supervision of these centers and for certain

medical and nursing duties. The communicable diseases must be promptly identified and isolated; isolation facilities must be provided; kitchens, buildings and grounds must be kept clean and the food supply protected against contamination; adequate toilet, bathing and laundry facilities must be provided; and the general sanitary standards and regulations of the local and state health departments carefully observed. These are definite responsibilities of the Red Cross health and medical service.

The accompanying chart attempts to show the administrative set-up of Red Cross public health and medical activities in disasters, and how each division functions in relation to local health departments, the medical profession and the nursing and hospital services. The chart does not attempt to outline the activities of health departments or other local groups, but outlines only Red Cross duties and indicates how they are correlated to the activities of local agencies.

It is of prime importance that health department and Red Cross public health activities in disasters are carefully coördinated. There should be no overlapping or duplication of services, or misunderstanding of purpose. This necessitates bringing these agencies together to study the problem; to formulate policies and working agreements; to define the function and duties of each; and to prepare routine inter-relating procedures. Unless this is done we cannot hope to have one public health program in disasters.

Mexico Child Health Work

THE Division of Infant Hygiene, *Service de Higiene Infantil*, was established by the Federal Department of Public Health of Mexico early in 1929. In recent years this department also established prenatal clinics in the capital and in the states. Child health centers have been in existence since 1921, and since the organization of the Division of Infant Hygiene, 5 new child health centers have been established where prenatal advice is also given. The centers, situated in the poorer districts, all have modern equipment and are staffed with physicians and nurses. Treatment in case of illness is also given to mothers and children, although the main purpose is the prevention of illness. The Division of Infant Hygiene also maintains a staff of visiting nurses who visit the mothers to see whether they comply with the physicians' directions and to persuade them to attend the centers regularly. A school of child care (*Escuela de Puericultura*) is maintained, in which courses are given for physicians, nurses, school teachers, and housewives.

The Division of Infant Hygiene is also coöperating with the *Asociación Nacional de Protección a la Infancia*, a recently organized private society, which maintains a maternity home and several nurseries and is planning to establish new child health centers. This association has established child health agencies in various states.—*El Niño, Revista Mensual*, Mexico City, Jan., 1930, p. 64.

Bacterial Aftergrowths in Water Distribution Systems*

THE Committee on Water Supply has directed its efforts during the past year largely to a consideration of the above subject. It is known that a few cities throughout the country are having trouble with what appear to be growths of *B. coli* in the water after it leaves the purification plant, or the point where the water is chlorinated. The *B. coli* content of the water in some cities has, at times, been found so high in certain parts of the distribution system that it leaves doubt as to the safety of the water for drinking purposes. This is especially true where the *B. coli* content is the sole standard of quality.

Consideration is given here to causes of aftergrowths and not to pollution. Any water may become polluted if the proper protections are not provided, but it is believed that there must be some special condition to cause *B. coli* to increase materially in water. We hope that finding the conditions under which it will increase will enable many cities to apply a remedy.

To obtain some idea of the extent of troubles from bacterial aftergrowths, a questionnaire was sent to 90 cities throughout the country. Forty-eight replies were received, most of which were from the larger cities. The estimated population of those to which the questionnaire was sent is about 30 millions, and the 48 replies were from those having a combined population of 25 millions. No attempt was made to make the questionnaire complete. The committee desired most of all to find places where aftergrowths were occurring. The replies may not represent the actual conditions in many instances, but give some information of value. Fourteen cities, with an estimated population of nearly 16 millions, reported that they were having or had had trouble from bacterial aftergrowths. A few others reported increases in bacterial counts after some disturbance in the mains, or occasionally in dead ends.

The following is a brief digest of the essential facts as reported by the cities having trouble from bacterial aftergrowths, or which would have trouble if the water were not treated especially to prevent them:

Albany, N. Y., has 2 open reservoirs with capacities of 7 and 30 million gallons. They are lined with brick with riprap at the top. The storage periods are about

* Report of the Committee on Water Supply, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

½ day and 2 days. The water levels are above the level of the surrounding ground. Microorganisms do not grow abundantly in the reservoirs and they are not being treated to prevent such growths. The bacterial increase in the distribution system is not due to cross-connections with polluted supplies.

"There is no question but that the increase in coli in the distribution system comes from coli entering the open reservoirs from fecal matter from rats, birds, and swimmers that make use of the reservoirs, notwithstanding the fact that they are well lighted and patrolled up to 11 P.M. The increase in coli starts in May with the advent of warm weather and persists well into October when the water cools. The filtered water entering the reservoir has been free from coli for 5 years in 10 c.c. portions. The water in the mains served by the reservoirs shows the presence of confirmed coli in 75 per cent of the 10 c.c. portions."

Baltimore, Md., has 8 open reservoirs with capacities of 5, 15, 20, 22, 24, 35, 195 and 500 million gallons. Four of the reservoirs are lined with concrete and 4 with stone riprap. Six have the levels of the water above that of the surrounding ground and 2 have the ground above that of the water on two sides. The 500 million gallon reservoir is not in regular service. The water is treated with hypochlorite of lime for the reservoirs in use. When the large reservoir is used the water is chlorinated. There is no excessive pollution from the air. Microorganisms would grow in some of the reservoirs, but such growths are kept down by the hypochlorite of lime or by copper sulphate. Cross-connections with private supplies are not permitted.

Buffalo, N. Y., has 1 open reservoir with a capacity of 116 million gallons. It is lined with stone. The storage capacity is about 2 days. The water level is above that of the surrounding ground. There is the possibility of pollution from the air. Algae do not grow abundantly, and the reservoir is not being treated. The *B. coli* in the distribution system is not due to the reservoir.

"Marked increases in the bacterial counts in the distribution system occur during the summer months when the temperature of the water runs between 65 and 72° F. By increasing the normal average dose of 0.20 p.p.m. of chlorine to an average of 0.30 p.p.m. the growths are kept well in control."

Charleston, S. C., has 1 open reservoir with a capacity of 2.5 million gallons. It is lined with brick. The water level is above that of the surrounding ground. It is possible for the water to be polluted from the air. Algae grow during the summer months. The reservoir is not in regular use, and when used the water is sterilized. Occasional increases in the bacterial counts are attributed to breaks in the mains or to heavy drafts such as may be caused by fires.

Chicago, Ill., has no open reservoirs. The water is chlorinated at the pumping stations to the extent that residual chlorine extends over the entire distribution system. If this were not done there would be bacterial increases beyond the zone of residual chlorine.

Cincinnati, O., has 2 open reservoirs with capacities of 35 and 96 million gallons. The water level is above that of the surrounding ground for the 35 million gallon reservoir and below for the 96 million gallon reservoir. There is not much pollution from the air. Water from the larger reservoir shows considerable increase in *B. coli* from about April to November each year. This reservoir has fairly abundant algal growths during the warmer months. The bacterial results for 1927 and 1928 are summarized in Table I. Clarence Bahlman gives additional information on bacterial increases.¹

TABLE I

COMPARISON OF PRESUMPTIVE *B. COLI* INDEX PER 100 C.C. IN PLANT OUTPUT,
HIGH SERVICE AND LOW SERVICE DISTRIBUTION SYSTEMS,
CINCINNATI WATER WORKS

Month	Plant Output	1927		Plant	1928	
		High Service	Low Service		High Service	Low Service
Jan.	0.36	0.00	0.16	1.13	0.23	0.69
Feb.	0.11	0.00	0.05	0.58	0.00	0.69
Mar.	0.00	0.00	0.00	0.19	0.73	0.38
Apr.	0.33	0.33	0.16	0.10	1.09	1.17
May	0.03	0.83	1.33	0.00	0.00	2.94
June	0.10	0.15	1.64	0.20	0.15	4.14
July	0.00	0.33	2.14	0.45	0.00	3.89
Aug.	0.23	0.46	2.20	0.42	0.55	2.84
Sept.	0.37	0.13	1.08	0.17	0.80	1.65
Oct.	0.13	0.62	1.95	0.03	0.33	1.19
Nov.	0.03	0.00	1.81	0.43	0.22	0.85
Dec.	0.29	0.15	0.46	0.13	0.00	0.30
Av.	0.17	0.25	1.08	0.32	0.34	1.73

Detroit, Mich., has no open reservoirs, but there are occasional bacterial increases in the dead ends.

New York, N. Y., has 13 open reservoirs (2 not in use) with capacities up to 1,000 million gallons. Some are lined with concrete, some with brick, and some with clay or mud. The water levels are above that of the surrounding ground. They are occasionally polluted from the air by smoke, street dust, sea gulls and other birds. Microorganisms grow abundantly at times. The water is treated with copper sulphate when necessary. Water from the reservoirs occasionally shows an increase in *B. coli* in the late summer. *B. coli* and *B. welchii* are present in the mud at the bottom, growing on organic matter such as dead microscopic organisms. *B. coli* is present in the sediment of all mains. Any disturbance of the flow will cause *B. coli* to appear in the taps.

Pittsburgh, Pa., has 7 open reservoirs with storage of about 3 to 3½ days. The reservoirs are lined with concrete, and the water levels are above that of the surrounding ground. Bacteria increase in only one section of the city. Microorganisms do not grow abundantly in the reservoirs. The water in the reservoirs is not being treated. Cross-connections with private supplies are not responsible for the increase in bacteria. There is no evidence that the open reservoirs are responsible for the increase.

Philadelphia, Pa., has 3 open reservoirs with capacities of 40, 70, and 680 million gallons. They are lined with asphaltic coating on brick or concrete. Two smaller ones are balancing reservoirs, and the large one is a storage reservoir which is not in regular service. The water levels are above that of the surrounding ground. The balancing reservoirs feed only a small portion of the system. Bacterial increases occur only when the system is disturbed, or when the water is drawn from the storage reservoir. Microorganisms occasionally grow abundantly in the reservoirs in hot weather. There is no pollution from cross-connections. Copper sulphate is used occasionally in hot weather. Water from the large storage reservoir is chlorinated when used.

Washington, D. C., has 4 covered reservoirs with capacities of 8 million gallons each. They are lined with concrete, and the water levels are above that of the surrounding ground. Bacteria do not increase to any extent in the distribution system. One open reservoir, now out of service, formerly caused bacterial aftergrowths. Carl J. Lauter gives a detailed account of the aftergrowths caused by this reservoir.²

City No. 1—There are 7 open reservoirs with capacities ranging from 2 to 4 million gallons. They are lined with masonry, and the water levels are above that of the surrounding ground. Microorganisms do not grow abundantly in the reservoirs. There are occasional increases in the bacteria. The water in the reservoirs is chlorinated intermittently. There are no cross-connections.

City No. 2—There is 1 open reservoir with a capacity of 14 million gallons. It is lined with concrete, and the water level is above that of the surrounding ground. Microorganisms grow in the reservoir, but it is chlorinated to prevent such growths. There is no pollution from cross-connections. For the year 1928, 11.2 per cent of the 10 c.c. tubes from the reservoir showed *B. coli*, whereas only 1.6 per cent of the 10 c.c. tubes from the water delivered to the mains showed *B. coli*.

City No. 3—There are 3 open reservoirs with capacities of 6, 6, and 12 million gallons. They are lined with concrete, and the water levels are above that of the surrounding ground. A heavy dose of chlorine is used when the reservoirs are filling. Considerable dust blows into them. Chlorine and copper sulphate are used to prevent microscopical growths. There is considerable trouble from bacterial aftergrowths from March to November. There is no pollution from cross-connections. The aftergrowths are attributed to the open reservoirs.

Thirteen cities with one or more open reservoirs reported no bacterial aftergrowths. In response to the question, "Do you have any evidence of increase in *B. coli* in the distribution system from sections where there is no possibility of the water coming from an open reservoir?" 5 cities replied in the affirmative. Two or 3 have noted occasional increases, but attribute them to causes other than growths in the mains.

There are 48 open reservoirs in the cities reporting bacterial increases. There is no definite information as to how many of these contributed to the bacterial increase. There is no positive evidence that such increases constitute a menace to health, yet there is no way of telling just how much was due to pollution and how much to aftergrowths. Bacterial increases, especially in *B. coli*, tend to render unreliable our main criterion for judging the safety of water. When there is the possibility of pollution, as there is for all open reservoirs, the increase in *B. coli* content should not be ignored even though there is good evidence that it is due to the *B. coli* growing on decaying microorganisms.

The *B. coli* content of the water need not be the sole standard of quality, but the same factors that are used in judging the quality of

the water entering the distribution system should apply to the water from all open reservoirs, tanks and standpipes. Sampling points should be established throughout the distribution systems so that the water from all reservoirs, tanks, etc., will be tested with a frequency that will insure a fairly good check on the quality.

The committee would urge that more study be given open reservoirs throughout the country by the various water departments with the hope of reducing the number to a minimum. Enough information is now available to throw doubt on the wisdom of using open reservoirs without continuously chlorinating the water. *B. coli* growing on microorganisms does not constitute a menace to health, but if we become accustomed to assuming that bacterial increases in the distribution system are natural growths and of no significance the occasional occurrences of real pollution will also be ignored.

DISCUSSION

CHESTER COHEN

*District Sanitary Engineer, State Department of Health,
Austin, Tex.*

WE are sometimes prompted to attempt to apply a varying interpretation—a different yardstick—to the bacterial results expected to be obtained from a deep and adequately protected well water supply, from a surface supply only partially treated, and from a long stored and completely treated surface water. This differentiation would, of course, complicate the problem, especially where we could not be sure of the previous condition of the mains, or their thorough sterilization prior to installation.

Our most recent experience at Laredo in dealing with a gas forming organism in the mains led us to imagine some weakness in the purification process of the turbid, highly organic, and difficult Rio Grande water. A further examination of the particular organism by Mr. Umbenhauer, indicated its particular resistance to chlorine treatment as shown in Table I.

This organism proved to be an aerobic, spore forming, rod-shaped bacillus, forming gas only after 24 hours' incubation, and producing an atypical green sheen growth on eosin methylene blue agar. In such a case we find it a little difficult to take a consistent and yet practical viewpoint. It is obvious that large chlorine

TABLE I

Chlorine Treatment	Residual Chlorine after			Chlorine Contact Period and Gas Formation in Broth					
	1 hr.	2 hr.	5 hr.	5—15—30 min.			60—90 min.		
0.5 p.p.m.	—	—	—	+	+	+	+	+	+
1.0 "	—	—	—	+	+	+	+	+	+
1.5 "	0.4	0	0	+	+	+	+	+	+
2.0 "	—	0.5	0.25	+	+	+	+	+	+
2.6 "	—	0.66	0.3	+	+	+	+	+	+
5.1 "	—	1.0	0.5	+	+	0	0	0	0

doses and long contact periods would be required to bring such a supply within the standards of the partially confirmed test.

A. F. Allen, writing from Coral Gables, advises us that although the original well supply there is usually free of *B. coli*, and although the chlorinated water at the plant was entirely free, yet occasional main samples show its presence in the completed test. These organisms are non-sporeformers and of the non-fecal type.

Much the same problem exists at Houston, although here an occasional spurious *B. coli* type occurs in the untreated well water, as well as in the distribution system. But here, too, the problem seems to be more a question of aftergrowth in the mains, either as a result of organisms passing the sterilization unit, or as a residual bacterial contamination existing in the system and remaining unaffected by the very slight or negative chlorine residual carried in the water when it reaches the far ends of the mains. An example of this condition is shown in Table II taken from the Houston analyses, where the city meter is the origin of the water supplied to wharves 11 and 12.

TABLE II

BACTERIOLOGICAL DATA FOR MONTH OF AUGUST

	City Meter Sta. No. 23	Wharf No. 11 Sta. No. 21	Wharf No. 12 Sta. No. 22
10 c.c. tubes showing gas formation	8	12	3
10 c.c. tubes showing confirmed <i>B. coli</i>	4	7	1
No. of samples examined	16	16	17
Per cent of tubes showing gas	10.0	15.0	3.54
Per cent of tubes confirming <i>B. coli</i>	5.0	8.75	1.18

BACTERIOLOGICAL DATA FOR EARLY SEPTEMBER

10 c.c. tubes showing gas formation	0	6	2
10 c.c. tubes showing confirmed <i>B. coli</i>	0	6	2
No. of samples examined	4	4	4
Per cent of tubes showing gas	0.0	30.0	10.0
Per cent of tubes confirming <i>B. coli</i>	0.0	30.0	10.0

From these preliminary data we see an indicated trend toward positive improvement at the city meter where water is being furnished to the wharves, but at the same time notice, not only a corresponding lack of improvement, but an actual lowering in the sanitary quality of the water supply at these two wharves.

In a way we regret the confusing results due to bacterial aftergrowths, since they very seriously tend to cast a doubt on the reliability of the *B. coli* test as a criterion for judging the sanitary quality of a water supply. The apparent multi-

plication of these doubtful organisms and their increasingly noticed occurrence in the distribution system is becoming most confusing to the average water plant operator and bacteriologist.

We find that the plant operator after a period of doubt and extra careful operation of his purification control process, becomes discouraged and somewhat disgruntled if his distribution system samples do not equal those taken direct from the plant. He usually concludes by assuming that the bacteriological test is unreliable and only a waste of time and effort.

While we cannot agree with such a conclusion, we do believe that overemphasis can be laid on the bacterial occurrence of gas forming organisms in the distribution system. We would be more inclined to lay special emphasis on the quality of the water as placed in the mains at the pumping plant. If regular and consistent samples of the treated water going into the mains indicated freedom from polluting organisms, and if no later polluting sources, such as cross-connections or open reservoirs, exist, we would ordinarily expect the supply to be satisfactory for domestic use. Where the above conditions obtained, we have never been able to demonstrate any *B. coli* organisms among the gas forming aftergrowths in the distribution system.

Medical Research

IT is strange how often religion, or what is alleged to be religion, is made the basis of intolerance. To pass from the sublime to the ridiculous, from the Inquisition to the present day, even a parish magazine may be used as the vehicle for anti-vivisection propaganda. In the *Parish Paper* of the Church of St. Jude-on-the-Hill (Hampstead Garden Suburb) of May 24th, 1929, the Rev. B. G. Bouchier permitted himself to ask "intelligent people" to take the opportunity of the General Election, now past, to put an end to "the waste of public money" involved in medical research. He protested there against the expenditure of 148,000 pounds during the last financial year by the Medical Research Council.

Those of us who know the admirable use to which that money is put, in promoting medical knowledge and therewith the health and happiness of the community, would wish a formal protest to be made against such propaganda in such a place. The reverend gentleman is entitled to hold whatever private opinions he chooses about the personal characters and abilities of those engaged in medical research; the use, however, of his authority and position in the national church as a means of hindering the work of an organisation which is serving mankind, at least as well as he is, is a disgrace which the authorities of that church would do well to note. It is as though the Medical Research Council were to permit an attack upon the Church of England and its priests to be launched by one of its junior workers in the pages of a Report!—From "Enemies of Knowledge," by Professor A. V. Hill, *The Quarterly Journal of the Research Defence Society*, Summer, 1929, pp. 12-13.

Bacteriological Basis for the Effective Pasteurization of Ice Cream*

THE demand from the public and the trade that ice cream be produced and handled as cleanly as milk has resulted in the endeavor to lift certain phases of milk control bodily over into the ice cream field without always giving consideration to the fact that ice cream is different from milk and therefore may have to be handled differently in some respects. However, in view of our great success in improving the quality of our milk supplies it behooves us to retain in our ice cream control all those items which are clearly applicable. Where a reasonable doubt exists as to such applicability, the question should be subjected to experimental tests.

Last year Dr. W. H. Price summarized¹ our knowledge concerning the significance of *B. coli* in ice cream. He concluded that:

Much remains to be cleared up before we can interpret the coli test properly. . . . In the case of ice cream, the colon test has limitations in determining the efficiency of pasteurization, as it has also in determining the introduction of contamination after pasteurization. . . . We find a generally accepted opinion that the tests for *Bacterium coli* in ice cream require a thorough knowledge of the previous history of the sample to enable any proper interpretation. Such tests cannot, in the present state of our knowledge, serve as a measure of manurial pollution or as a measure of the efficiency of pasteurization. Neither do they contribute to the detection of pathogens nor to the prevention of disease transmission. *Bacterium coli* determinations may indicate that the dairy product under examination has been kept under conditions favorable to the development of bacteria commonly found in milk. The same conditions are disclosed by the Standard Plate Count, and the Direct Microscopic Count, both of which have the advantage of common acceptance and application. . . .

Irwin comprehensively reported² on the present status of ice cream sanitary control and showed that the states and municipalities differ in pasteurization requirements over a range from 142° F. for 25 minutes to 185° F. flash.

Zoller,³ after an extensive inquiry to 500 ice cream companies, to which he received 179 replies, reports the temperatures and holding periods range from 140° F. for 30 minutes, to 165° F. for 30 minutes and up to 185° F. for 10 minutes, with all sorts of intermediate com-

* Report of the Committee on Dairy Products and Eggs, presented to the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

binations of temperatures and times. Seventy firms used 145° F.; 33 used 150° F.; and 12 used 160° F. all for 30 minutes.

It is generally known that several municipalities require a pasteurization temperature of 160° F. for 30 minutes, and some as low as 140° F.

In the absence of any known experimental work to demonstrate a proper temperature and time for pasteurizing ice cream, health officers have either literally followed their milk control procedure, or have assumed that, on account of the greater content in ice cream of solids (especially fat) with its presumably protective effect, the temperature must be raised to some undetermined point. They invoked the *B. coli* count, as used and interpreted in milk control, and set the requirements to be such as they thought would kill *B. coli*.

The reasonableness of assuming a protective influence by the increased solids in ice cream and the fallacy of expecting to kill all *B. coli* as a measure of effective pasteurization have recently been experimentally elucidated.

Beavens⁴ has just shown that the death points of certain strains of *B. coli* which had previously been found to lie between 143–144° F. for 30 minutes, actually were raised above 145° F. for 30 minutes when 4–20 per cent lactose was added to the broth. He quotes Robertson⁵ that hypertonic solutions have a protective effect up to and including 50 per cent sucrose. He agrees with the earlier workers that "the coli test is not a true index to proper pasteurization of milk."

Since the publication of Price's review,¹ Tanner and Windsor,⁶ working with milk, studied 23 strains isolated from human intestines, water and sewage, and reported:

Although neither the *Escherichia coli* (*Bacterium coli*) cultures nor the *Serratia marcescens* (*Bacillus prodigiosus*) strains used proved to be very good as indicators of efficiency of pasteurization by the holder process, for several reasons the *Escherichia coli* (*Bacterium coli*) would probably prove to be more accurate as such an indicator. It seems fair to assume . . . that *Escherichia coli*, in concentrations in which it occurs in milk, would be destroyed by exposure to 62.8° C. for 30 minutes, yet there is always the possibility of encountering resistant strains or cultures containing some resistant cells.

They thus align themselves with the preponderance of authoritative opinion that the coli destruction is not always a reliable measure of the effectiveness of milk pasteurization. Since hypertonic solutions exert a protective effect, then the coli count in ice cream, used as in milk control, is all the more unreliable.

As a matter of fact, we are not interested in the destruction of the coli organisms as such, but only as they may be easily demonstrable and possibly significant companions of pathogenic organisms which

are not easily demonstrable. If it were shown that pasteurization of commercial ice cream at 145° F. for 30 minutes is ample to kill all pathogenic organisms, then the usefulness of the coli determination would become clearly of little consequence. This information has just now been supplied.

Oldenbusch, Frobisher and Shrader⁷ inoculated cream with two strains of *B. typhosus* recently isolated from cases; two strains of beta type hemolytic streptococci, one from scarlet fever, the other from septic sore throat; and a culture of tubercle bacilli of the bovine type. All of the organisms were killed in less than 7 minutes at 142° F. and in less than 3 minutes at 145° F.

They conducted similar experiments on a commercial ice cream mix, and found that *B. diphtheriae* did not survive heating for ½ minute at 145° F.; *B. typhosus* and the streptococcus were killed in less than 5 minutes; and the tubercle bacillus in 6 minutes at 145° F., and 3 minutes at 150° F.

In comparing these two sets of experiments, a slightly greater resistance was encountered in the case of the ice cream mix as compared with the cream.

Inasmuch as the number of pathogenic organisms involved was much greater than would obtain under natural conditions of contamination, they conclude that the time and temperature of 30 minutes at 143.5° F. recommended by the Committee on Dairy Products and Eggs of the American Public Health Association for the pasteurization of milk allows an ample margin of safety for the pasteurization of cream and of commercial ice cream mix.

From all of this work it follows that the *B. coli* is no more useful in determining the proper pasteurization procedure for ice cream mix than for milk. Direct work with pathogenic organisms certainly shows that a temperature of 145° F. for 30 minutes is a proper procedure for ice cream mix pasteurization.

Study of the Effects of 736 Tonsillec- tomies and of 741 Controls*

JOHN D. MONROE, M. D., AND V. K. VOLK, M. D., DR. P. H.

*Commissioner of Health and Deputy Commissioner of Health, Oakland County,
Pontiac, Mich.*

IT is impossible to think of any operation or procedure which is as commonly resorted to for the correction of any and all defects or complaints as is a tonsillectomy. Our search through available literature on the subject reveals an abundance of material and an almost universal opinion that good results, both curative and preventive, are to be expected.

Kaiser, of Rochester, N. Y., has done a very thorough and gratifying piece of work with convincing conclusions.

Besides verifying the figures and results obtained by Kaiser, Barrett, Robey, Mann and others, we have drawn some conclusions as to:

1. The age group which shows the greatest improvements and the complaints, if any, which can be relieved to the greatest degree in the respective age groups.
2. The length of time after operation before improvement is evidenced and the symptoms showing the earliest tendency toward improvement.
3. The effect on the school progress of those being physically handicapped.
4. The effect on children with subnormal mentality or those who are mentally retarded and lack application and alertness.
5. The effect of tonsillectomies on the progress of children having coexisting conditions related and not related to diseased tonsils.

It has been suggested by Brokay and others that the parents should be consulted as to the child's condition following the operation. In our study the parents' opinions were obtained in each case. We believe that information secured through the parents' daily observation is likely to be more dependable than that which might be secured from any other single source; however, the teachers' observations were not overlooked. We were also mindful of the fact that this information should be supplemented by physical examinations before and after operation.

This study was based on cases operated on by private physicians

* Read before the American Child Health Association and the Child Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., September 30, 1929.

in the Oakland County Tonsil and Adenoid Clinics together with a small number of cases operated on in other clinics.

Oakland County's tonsil and adenoid clinic was organized because of the difficulty and expense of caring for indigent children in state institutions, and because of the lack of outpatient departments in our city and county hospitals. Each case, before admission to the clinic, was first recommended by the family physician both from the medical and financial standpoint, then carefully investigated by our field workers and by the Township Supervisor. Indigent patients and those who were able to pay up to \$10.00 were admitted. The tonsillectomies were performed by local surgeons at greatly reduced fees, and we gratefully acknowledge the support given the clinic by the Oakland County Medical Society.

A careful history was taken and a physical examination made on each child upon admittance, and through this arrangement 736 cases were operated on and studied.

In determining the candidates for the clinic and for follow-up work, uniform blanks were used.

It was determined early in the study to check carefully the improvement rather than the complete cessation of complaints or symptoms. Although in many cases the symptoms or complaints were entirely absent after the operation, it seemed reasonable that our study be confined solely to improvements.

A study was made of the effects of tonsillectomies upon children who were not gaining weight and not developing normally, those with evidence of malnutrition, those with marked enlargement of cervical glands, those with rheumatic manifestations, those who complained of colds and sore throats, and those with retarded school progress and subnormal mentality.

In Figure I, we have a general summary of cases studied before and after operation. There was apparently no complaint or symptom which failed to improve. In our study of cervical glands, only cases which showed marked enlargement were considered, and out of 191 cases studied, 48 children failed to show improvement. The most striking improvement occurred in the group having frequent colds and sore throats. Of the total number studied, 530 cases, or 72 per cent, had this complaint before the operation, with 102 failing to show any improvement.

The enthusiasm of the mothers in regard to the children's progress in school following the operation was very marked. Of the 222 children having this complaint only 88 failed to show improvement.

We were somewhat surprised to note the effect of this operation on the group of subnormal mentality. Out of 148 cases in this group 57

FIGURE I

STATUS OF COMPLAINTS BEFORE AND AFTER OPERATION

failed to show improvement. There was a marked improvement in cases with evidence of malnutrition. One hundred eighty-eight, or 25.5 per cent of all cases studied, showed this complaint, and there was a failure of improvement in only 73 of this group. The same beneficial results were noted in children not gaining weight or not developing normally, and in those having rheumatic manifestations.

STUDY BY AGE GROUPS

In studying the beneficial effects on children grouped according to age (see Figure II), no striking results were obtained. The most marked improvement of all complaints was observed in the younger age groups.

Failure in older age groups (13 and over) can be accounted for in many ways. The longer any ailment persisted the less marked the improvement; it was only natural for the older age group to be less responsive to improvement in school progress and mental efficiency than children in the younger age groups.

STUDY OF RESULTS BY TIME LAPSING SINCE OPERATION

In this study we have drawn some conclusions as to how soon after operation improvement may be expected. From the figures

FIGURE II

STATUS OF COMPLAINTS BEFORE OPERATION WITH NUMBER OF FAILURES GROUPED ACCORDING TO AGE

shown in Figure III, children who were not gaining weight and were not developing normally before the operation showed a little improvement during the earlier months, reaching the peak of improvement about 16 to 18 months after operation. There were no marked beneficial results in children showing signs of malnutrition, although a failure of only 36.5 per cent during the first 6 months was gratifying.

As was expected, improvement in the marked enlargement of cervical glands was not characteristic to any period. Rheumatic manifestations showed remarkable improvement during the first 6 months. Frequent colds and sore throats were decidedly improved during the first 6 months following operation. Advancement in school progress and mental development was not marked during the first 6 months after operation but there seemed to be consistent progress in the periods which followed.

FIGURE III

STATUS OF COMPLAINTS BEFORE AND AFTER OPERATION WITH FAILURES GROUPED ACCORDING TO TIME ELAPSED SINCE OPERATION

We have not tabulated the relief from mouth breathing as the study has been done many times by others with most convincing results.

General progress of those cases showing improvement in one or more complaints was very noticeable, the most outstanding results being obtained during the first 6 months. Out of 192 cases in this age group, there were 12 failures (6 $\frac{3}{10}$ per cent), or 93.7 per cent of the cases showed complete or partial improvement.

STUDY OF RESULTS IN PRESENCE OF COEXISTING CONDITIONS

We have analyzed the results of tonsillectomies on children who at the time of operation had some coexisting ailment.

From the group of 736 children who were operated on, 120 had coexisting conditions. In the analysis of the results of operation on this group (see Table I), we found that 43 failed to improve, and 77 showed improvement.

We have failed to find that coexisting ailments had any influence upon the results of the operation with the possible exception of pulmonary tuberculosis.

From the table it will be seen that in this group there were 26

FIGURE IV

A

B

C

D

cases of pulmonary tuberculosis, 16 of which failed to improve. Considering that the number of cases failing to show improvement is almost twice as great as the number showing improvement, the ratio of failure to improvement would be 2 to 1. The figures, of course, are too small to do more than bear out the consensus of opinion that great care should be exercised before determining whether or not the child with pulmonary tuberculosis should be operated on.

TABLE I

ANALYSIS OF RESULTS OF OPERATED CASES IN WHICH COEXISTING
AILMENTS WERE PRESENT AT TIME OF OPERATION

Total Number of Cases 120

Conditions Present	Total Number of Children	Number Failed to Improve	Number Showed Improvement
Pulmonary Tuberculosis	26	16	10
Heart	7	1	6
Ear	16	5	11
Chorea	5	2	3
Dental (marked defects)	20	7	13
Infectious Diseases following within 10 days	5	3	2
Sinus	13	5	8
Hay Fever—Asthma	2	1	1
Kidney	7	2	5
Nervousness	9	0	9
Surgical	8	1	7
Gynecological	2	0	2
Total	120	43	77

This table, with the one exception mentioned, shows us that co-existing conditions are not contraindications for operation. As a matter of fact they might even be additional reasons for operation.

STUDY OF CONTROL GROUPS

In our control group (see Figure IV), we have examined 741 children whose state of health was apparently similar to that of those in the group operated on.

The general progress made by the children in the control group was, as would be expected, unsatisfactory. Children with infected tonsils retained the focuses of infection and the symptoms and complaints which were present at the time of the first examination were still apparent at the check-up made a year later.

Careful analysis of Figures V—A, B, C, and D, leads us to assume that the theory of waiting for the child to outgrow its defects is not justifiable.

SUMMARY AND CONCLUSIONS

From an analysis of the complaints of 736 children before and after operation, compared with an analysis of the complaints of 741

children in the control group having similar complaints on examination and reexamination one year later, the following conclusions were made:

1. Tonsillectomy offers a child considerable relief from such common complaints as sore throat, head colds and mouth breathing. It reduces malnutrition and promotes disappearance of enlarged cervical glands.
2. Complaints have been relieved in 91 per cent of our group of cases operated on. We should not be unmindful of the fact that tonsillectomy is a surgical procedure and has its possible dangers and complications. However, in the group of cases operated on in our County Tonsil Clinic no fatalities have occurred.
3. Comparison of the results obtained from a study of the different age groups clearly indicates that in order to obtain the maximum benefit the child should be operated on in early childhood.
4. Children with subnormal mentality and retarded school progress due to enlarged tonsils and adenoids showed improvement in 40 per cent of all cases operated on.
5. In our series of 736 cases, coexisting conditions were present in 120 cases. The conditions should not be considered as contraindications for tonsillectomy, with the exception of cases of pulmonary tuberculosis which must be very carefully studied before operation is decided upon.
6. Complaints in the control group of cases do not show any improvement during the period of one year of observation as compared with 91 per cent of improvement shown in the group of cases operated on.

The Minimal "Chlorine Death Points" of Bacteria*

II. Vegetative Forms III. Spore-Bearing Organisms

FRED O. TONNEY, M. D., F. A. P. H. A., FRANK E. GREER,
F. A. P. H. A., AND GEORGE F. LIEBIG, Jr.

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

THE results of continued tests on vegetative forms and on the common spore-bearing bacteria are presented in this paper, with a more detailed description of the technic employed.

TECHNIC

Preparation of the Chlorine Solutions—Double distilled water in a pyrex or Jena flask was saturated with chlorine gas from a tank of liquid chlorine made by electrolysis for the treatment of water supplies.† From this, five stock solutions were made, containing 10, 50, 100, 200 and 500 p.p.m. These were stored in brown glass stoppered bottles in an icebox and restandardized every 2 weeks.

From the stock solutions the experimental dosage solutions were prepared with double distilled and sterilized water in 250 c.c. pyrex or Jena flasks. The initial quantity of water in each flask was 150 c.c. Fifty c.c. were removed for the chlorine absorption test of the glassware and water. The remaining 100 c.c. portions of the dosage solutions were used in duplicate for exposure of the bacteria under test. One flask was tested bacteriologically and the other used for determination of the residual chlorine. Usually there was no material difference between the dose of chlorine introduced and the residual amount found, and the latter was, therefore, the amount recorded for the bactericidal experiment.

The chlorine absorbing properties of the water and glassware were determined just before the test proper by treating 50 c.c. of the water in each flask for 5 minutes with 0.3 c.c. of a stock solution of chlorine containing 60 p.p.m. After 5 minutes, $\frac{1}{2}$ c.c. of orthotolidin solution was added and the resulting color compared with standards. The water treated as above received 0.36 p.p.m. of chlorine. The amount

* This paper supplements an earlier report on the subject.²

† Obtained from Wallace and Tiernan, Newark, N. J.

of chlorine absorbed was usually negligible. If there was material absorption of chlorine by the water and glassware, the set was discarded. In no case were flasks giving a final content of less than 0.25 p.p.m. used in the experimental work.

The glassware was first carefully cleaned with sulphuric acid + potassium dichromate, and then rinsed several times with distilled water. The Nessler tubes used for the chlorine determination by the orthotolidin method were of uniform shade and selected carefully to give equal depth of solution. After each experiment they were rinsed thoroughly, filled with distilled water, and allowed to stand in this condition until again needed. Some lots of glassware were found to absorb appreciable amounts of chlorine and these were eliminated.

Method of Chlorine Determination—For the more concentrated solutions (above 5 p.p.m.), the iodine thiosulphate method was used as follows:

Twenty-five to 100 c.c. of the sample were diluted if necessary to 100 c.c. with the tested double distilled water, and to this solution 5 c.c. of potassium iodide (150 gm. per liter) and 1 c.c. of a solution of equal parts glacial acetic acid and water were added. The mixture was allowed to stand in a dark place for 10 minutes. It was then titrated with N/40 sodium thiosulphate to a straw-yellow color, when 1 c.c. of starch reagent was added and the titration finished.

For solutions containing less than 5 p.p.m. the orthotolidin method² was used. The color standards were made from copper-sulphate and potassium dichromate solutions.

Procedure of Bacterial Exposure—The technic of determining the "chlorine death points" of the organisms was essentially the same as that given in the previous report.¹ Nutrient agar plates were used for growing most of the strains, but special mediums were employed when necessary to secure growths. The Gram-negative cocci here included were grown on the modified Torrey's medium described by White and Pope³ for cultivation of the meningococcus.

The tests were carried out by adding approximately 100 to 300 organisms per c.c. to the contents of each of two flasks containing 100 c.c. of double distilled water which had just been tested for chlorine absorption. From one flask, 1 c.c. was planted to determine the number of organisms present, then a definite amount of free chlorine was added to each. One was tested for residual chlorine immediately after the experiment; the other flask was used for determining the rate of destruction of the organisms and the time required to kill. To do this 1 c.c. of the contents was plated at intervals of 10, 15, 30, 45 and 60 seconds. The plates were poured immediately, incubated for

48 hours at 37° C., the organisms counted, and the rate of destruction and time required to kill noted. It was found that 48-hour incubation was usually necessary, because in some instances colonies appeared after 48 hours on plates which in 24 hours had no visible growth.

RESULTS

II. VEGETATIVE FORMS

A brief summary of the previous work on vegetative cells is here included.¹ Two hundred and thirty-five strains, comprising 23 species, were tested. A large percentage of these strains were killed by 0.1 p.p.m. of free chlorine, in 15–30 seconds. None survived 25 p.p.m. *B. coli* stood out as in general the most resistant, and was deemed most suitable for use as an "index organism" of effective disinfection of vegetative cells by chlorination.

We have since chlorinated 126 additional strains including 8 new species, the results of which are summarized in Table I.

TABLE I

DOSAGE OF FREE CHLORINE REQUIRED TO KILL VEGETATIVE
CELLS OF BACTERIA IN 15–30 SECONDS

Chlorine p.p.m.	Species	No. of Strains	Chlorine p.p.m.	Species	No. of Strains
0.10	<i>B. aërogenes</i>	28	0.15	<i>B. aërogenes</i>	9
	<i>B. fecalis alkaligenes</i>	5		<i>B. coli</i>	5
	Gonococci	7		Meningococcus	1
	<i>M. catarrhalis</i>	3	0.20	Non-lactose fermenting bacteria from water	14
	Meningococci	25		<i>B. aërogenes</i>	4
	<i>B. mucosus capsulatus</i>	4		Non-lactose fermenting bacteria from water	3
	Non-lactose fermenting bacteria from water	18			
	<i>V. cholerae</i>	3	Total strains		126

Most of the vegetative strains, regardless of species, were killed by 0.1 p.p.m. of free chlorine. A few survived 0.15 p.p.m., and none required more than 0.20 p.p.m. for their complete destruction. Three hundred and sixty-one vegetative strains* have been tested, representing 32 species and including the more common pathogens. The later findings support our earlier conclusion that *B. coli* is probably the organism best suited for use as a criterion of effective chlorination of water supplies, swimming pools, dairy equipment, dishes and other utensils.

* Including previous work.²

SPORE-BEARING ORGANISMS

One hundred and forty-two strains of 17 species of spore-bearing organisms were studied. These, which included the more important pathogens and non-pathogens of both aërobic and anaërobic types, are shown in Table II.

The anaërobes were all grown in liquid beef heart medium except *Cl. botulinum A.*, *Cl. botulinum B.*, *Cl. sporogenes* and *Cl. welchii*, which were plated in the sulphite-glucose-iron agar of Wilson and Blair.⁴

B. aërosporus was grown on lactose agar. The other aërobes were grown on plain agar.

TABLE II

DOSAGE OF FREE CHLORINE REQUIRED TO KILL
SPORES OF BACTERIA IN 15-30 SECONDS

1. Anaërobes

Chlorine p.p.m.	Species	No. of Strains	Chlorine p.p.m.	Species	No. of Strains
1.0-2.5	<i>Cl. welchii</i>	25	25.0	<i>Cl. botulinum</i>	2
15	<i>Cl. tetani</i>	1		<i>Cl. tetani</i>	1
	<i>Cl. botulinum A.</i>	1		<i>Cl. chauvei</i>	1
	<i>Cl. chauvei</i>	1	30.0	<i>Cl. sporogenes</i>	1
	<i>Cl. sporogenes</i>	1	35.0	<i>Cl. chauvei</i>	1
17.5	<i>Cl. sporogenes</i>	18		<i>Cl. oedematiens</i>	1
	<i>Cl. botulinum B.</i>	4	40.0	<i>Cl. tetani</i>	1
18.0	<i>V. septique</i>	1			—
20.0	<i>Cl. sporogenes</i>	1			61

2. Aërobes

Chlorine p.p.m.	Species	No. of Strains	Chlorine p.p.m.	Species	No. of Strains
18	<i>B. aërosporus</i>	28		<i>B. cereus</i>	2
45-65	<i>B. anthracis</i>	6	160	<i>B. subtilis</i>	4
66-85	<i>B. anthracis</i>	21	190	Unidentified spore bearers from sewage	6
	<i>B. megatherium</i>	4		<i>B. vulgatus</i>	1
86-100	<i>B. anthracis</i>	5	280		—
	<i>B. mesentericus</i>	1			81
135-150	<i>B. mesentericus</i>	1			
	<i>B. brevis</i>	2			

There was wide variation in the amount of chlorine required to kill various species of spore-forming bacteria. For complete destruction, the anaërobes required a range of concentrations from 1.00 p.p.m. for the least resistant, *Cl. welchii*, to 40 p.p.m. for a strain of *Cl. tetani*. The aërobes required a higher and wider range of chlorine concentrations, varying from 18 p.p.m. for *B. aërosporus* to 280 p.p.m. for a strain of *B. vulgatus*.

DISCUSSION

These results demonstrate the futility of attempting to kill spore-bearing bacteria by use of chlorine in waterworks practice or in other phases of practical disinfection. The many times larger dosage of chlorine required to kill spores as compared to vegetative cells (10 to 1,100 times) would render the cost prohibitive, and cause a highly objectionable taste and odor in water supplies. Moreover, such excessive dosage seems unnecessary, since the essential purpose of the disinfection is the destruction of certain common pathogens of intestinal or respiratory origin, which belong to the group of vegetative forms, of which *B. coli* is the generally accepted group representative.

Should it be desirable under special circumstances to rely on the destruction of a member of the spore-bearing group as evidence of disinfection of spores, probably *B. subtilis* would be most suitable and safest to use. Its chlorine "death point" of 160 p.p.m. is higher than that of the common pathogens of the spore-bearing group and about 600 to 700 times that of *B. coli*.

In the light of the above findings, discretion should be used in adjusting the dosage of chlorine in water supplies on the basis of the gas tests, when lactose fermenting spore bearers are present. These organisms, which are widely prevalent in nature, require for their destruction amounts of chlorine ranging from 2.5 p.p.m. for *Cl. welchii* to 18 p.p.m. for *B. aërosporus*, or from 10 to 70 times that required by *B. coli*. *B. aërosporus* is so resistant to chlorine that its destruction in a water supply by chlorination cannot reasonably be expected.

Probably a residual chlorine dosage of 0.25 p.p.m., equivalent to the chlorine "death point" of *B. coli*, would be a safe margin to carry in water supplies under ordinary circumstances. In other words, the principle seems sound to require as a margin of safety, an excess of chlorine equivalent to the minimal "chlorine death point" of *B. coli*, after the primary chlorine demand of the water is satisfied. The same principle seems applicable to swimming pools; i.e., that 0.25 p.p.m. of residual chlorine would be a safe margin. This amount, if consistently maintained, should give assurance of the destruction of the common pathogenic bacteria here studied, which might reasonably be expected to find their way into water unless the conditions are very exceptional.

SUMMARY

In this and a preceding investigation, the "chlorine death points" or minimal amounts of free chlorine required to kill in 15-30 seconds were determined for 503 strains of 48 species of bacteria. The experimental conditions were adjusted to exclude as nearly as possible chlo-

rine absorbing factors other than the organisms, so that the relative resistance of the organisms to free chlorine would be indicated.

From the standpoint of resistance to chlorine, the bacteria studied fall into two major groups, (1) vegetative cells, and (2) the spore-bearing organisms. The vegetative group, including the common pathogens of both intestinal and respiratory origin (exclusive of the tubercle bacillus), were killed by small doses of free chlorine, i.e., 0.15 to 0.25 p.p.m. in 15 to 30 seconds. *B. coli* was found to be in general somewhat more resistant to chlorine than the other vegetative forms and was considered to be a suitable "index organism" for use as a criterion of effective disinfection by chlorine.

The spore-bearing group was found to be from 10 to 1,100 times more resistant to chlorine than the vegetative forms. The "chlorine death points" of spores ranged from 2.5 p.p.m. for *Cl. welchii* to 280 p.p.m. for *B. vulgatus*. *B. subtilis*, with a "chlorine death point" of 160 p.p.m., was considered to be probably best adapted and safest for use as an "index organism" of the spore-bearing group.

The wide divergence, however, in the resistance of spores on the one hand, and of vegetative cells on the other, suggests that in practical disinfection by chlorine, the attempt to secure consistent elimination of spore-bearers is futile, and serves to emphasize the primary purpose of such disinfection, which is, generally speaking, to safeguard against a relatively few pathogens of intestinal and respiratory origin belonging to the vegetative group. Considering these primary objects, the regular and consistent destruction of *B. coli* appears to afford a more suitable practical criterion of effective chlorine disinfection, than would a spore-bearing "index organism" such as *B. subtilis* or a total bacterial count which would be unduly affected by excessively resistant spore-bearing organisms of little sanitary significance.

Health Records of School Children in France

THE educational authorities of the city of Paris have decided to introduce into the public schools a system of individual health records which will permit regular supervision over the physical development and health of the children. The health records will be introduced in the elementary schools.—*Paris Méd.*, Feb. 1, 1930, p. XXV.

The Sanitary Aspects of Refuse Collection and Disposal*

FOUL odors are not now believed, as they once were, to be a direct cause of disease, but there is a growing appreciation of the fact that they indicate the presence of filth, and that filth is concomitant with a high incidence of disease and mortality. Civilized communities are therefore demanding greater freedom from what are generally termed "nuisances" in their various forms, offensive to sight or smell.

The sanitary aspects of the several steps involved in the handling of municipal refuse are here discussed:

I. HOUSE PREPARATION

The separation of garbage, combustible refuse, glass, metals and ashes depends upon the method of disposal. Separation at the source should conform to the method of collection. In exceptional cases, where separation at the source is impracticable, this may become a factor affecting the method of disposal.

Garbage—Garbage should be drained before putting it in the receptacle from which it is collected. Where local conditions indicate an advantage in wrapping the garbage in paper after draining and before putting it in the collection receptacle, this may be done. It should only be made compulsory after a study of local conditions and taking into account the method of final disposal to be employed. Garbage should not be wrapped if it is to be treated by the reduction process; nor if it is to be fed to hogs, since it will produce a very unsightly litter and add to the residue for final disposal at the feeding grounds. On the other hand there is a certain advantage if the garbage is to be incinerated and greater ease in keeping the cans clean.

Practically, whatever advantage there may be in wrapping garbage may be obtained by using a small garbage container supported on a swinging arm beneath the kitchen sink. This has an inner receptacle with a perforated bottom which does not reach to the bottom of the outer and water-tight container. If the garbage is properly handled before and while being placed in the inner container, very little moisture will go through. Whatever does may be emptied in the kitchen sink. The house container should be emptied in the outside collector-can and washed at least once a day.

Another simple type of container that has been found generally satisfactory for draining garbage is a small enamelware vessel with perforated sides and bottom, about 3" deep, in the shape of a quarter section of a circle so that it may be placed in one corner of a sink. It is usually provided with three short legs about 1½" long.

For multi-family houses with janitor service for removing the garbage of each

* Report of Committee on Refuse Collection and Disposal, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

family to the outside collector—can the foregoing rules and comments may need modification to meet local conditions.

Receptacles for holding garbage at houses and other buildings before it is taken away by the collector should be of metal, with metal covers, watertight and flyproof. They should be placed at some point readily accessible to the collectors, who should preferably come to the house for the garbage can instead of requiring the householder to take the can to the street.

The collection can should be kept covered, to exclude flies and other vermin, and rain water, and should be so placed that it will not be tipped over by dogs or other animals.

In some cases an ordinance requiring covered and water-tight cans has been difficult to enforce. In such cases the city may provide the cans, the cost of which should be considered as part of the cost of collection and not charged against the householder, as he might then be deterred from accepting the service of removal. The can, replaced by a clean one, is taken to the point of disposal or to a transfer station, where it is washed with hot water and disinfected if necessary.

If the contents of the collection can are kept dry by draining at the kitchen sink and by excluding rain water, the danger of offensive odor is reduced. If odors do occur, they can be remedied by the householder by occasional washing or other cleaning of the cans, and if necessary, the use of a deodorant and, on the part of the city, by prompt removal.

Ashes—Metal cans, of a size appropriate for the collection service, should be used as house receptacles for ashes. Economy to the householder and efficiency in the collection service demand that the cans be strong. No garbage or other decomposable organic matter or waste paper should be placed in the ash cans. Waste glass may be permitted in some cases.

Tins, Cans, Metal, Glass, Paper and other Combustible Refuse—Preferably these materials, if not too bulky, should be placed in strong metal receptacles, or else—except glass or sharp metals—in stout canvas bags. Large metal refuse boxes and cartons may be collected without placing in receptacles. If disposed of by incineration, heavy metals and glass should be excluded.

Single Mixed Collection System—Where garbage, mixed with ashes, glass, cans, paper and miscellaneous wastes generally are collected together, the house treatment will be similar to that for garbage. Where garbage is not included the house treatment will conform to the treatment for ashes.

On collection days the householder should put the containers out at some place readily accessible for the collectors. The exact place may vary with local conditions, single or multiple family dwellings, size of lot, position of house on lot, accessibility of rear yard, if any, presence or absence of alleys, but in general the preferable plan is to set the containers as near as may be to the street or alley entrance to the rear or side yard, leaving to the collectors the emptying or removal of the container and its return to the house.

II. TRANSPORTATION

The collection of municipal refuse and the method of disposal are closely connected and should be considered as a single problem. In some cases all classes of refuse are collected combined; in others they are collected and disposed of separately; and in still others they are collected and disposed of in part separate and in part mixed. In cases where part of the refuse is disposed of by incineration, the garbage and inflammable refuse may be mixed.

The collection of house refuse may be also classified as municipal, contract, and private. In municipal collection the refuse is collected by teams or trucks and employees of the municipality. In contract collection the refuse is collected by the employees and equipment of a private firm under contract. In some cases the refuse is collected by private individuals who are usually licensed by the municipality. There are also instances where the refuse is collected by the municipality and disposed of by contract and *vice versa*. It has been found that the sanitary features have sometimes been neglected under private and contract collection and disposal of refuse and that nuisances are often created, but this is not necessarily so with a properly prepared contract and specifications and strict supervision over the work.

The wagons or trucks in which the garbage is collected should be provided with smooth, water-tight metal bodies to prevent dripping or with metal barrels or containers. Wooden bodies or barrels should not be used as they absorb moisture from the garbage and soon become foul smelling and insanitary. For convenience in loading they should be hung as low as practicable. The metal bodies or barrels should be washed and disinfected daily and kept in good repair. While making collections, the wagon or receptacles should be covered to prevent spilling and the spread of odor. The service should be reliable and capable of expansion so that collections need not be delayed. It is advantageous to have the transport of the collected material as rapid as consistent with safety, as it reduces the time the loaded vehicles are on the street. In this respect truck transport is the best and horse-drawn transport the worst. The routing should be worked out so as to cause the least nuisance.

III. DUMPING ON LAND AND BURYING

Dumping on land is the simplest and most convenient method of disposal, but it is the method that most frequently results in a nuisance, and should therefore be carried out with great care and discrimination and under municipal control.

Ashes, including metals, glass and crockery, and containing not over 2 per cent of organic matter, may be profitably used in filling in low land or disposed of in dumps if remote from habitations and main lines of travel, where the dust may prove objectionable. Paper, boxes, etc., should be rigidly excluded, for they present an unsightly appearance and contain sufficient organic matter to invite the breeding of flies and the propagation of vermin, permit the dissemination of disease germs and, by burning, create far-reaching, pungent and offensive odors that under favorable conditions have been observed at a distance of 6 miles or more. This is a most prevalent source of nuisance in the outskirts of cities and one that calls for energetic measures for control.

Where other means of disposal are not provided, dumps of mixed refuse should be made, where the depth of fill exceeds 8' or 10', in layers not over 6' in depth. The garbage should preferably be deposited at the bottom, covered with rubbish and finally with ashes. Unless soil or other suitable material is available a sufficient amount of ashes should be allowed to accumulate during the winter to serve for this purpose during the summer months, when the proportion of ashes is small as compared with the garbage. The exposed fresh material at the face of the dump should be covered with at least 4" of soil or clean ashes at the end of each day during warm weather. Where necessary a temporary fence should be provided or other arrangements made to intercept papers that would otherwise be scattered by the wind. If active or smouldering fires occur, these should be im-

mediately extinguished, for which, in the case of extensive dumps, an ample and properly distributed supply of water should be provided. After getting headway such fires are very difficult to put out.

Refuse dumps should be in remote locations. They should not be made along the banks of streams, as is quite customary, for, aside from esthetic reasons, the impurities leaching or washing off into the water during storms add to its pollution and consequent injury for purposes of water supply, fish culture and recreation.*

Burying in trenches is generally limited to garbage. As the area required is large and as considerable labor is involved it is not practiced extensively. Otherwise it has been found generally satisfactory in small communities, especially where the soil is loose and sandy. Since decomposition is dependent upon the aerobic soil bacteria the garbage should not be buried so deep that the air cannot readily reach it. It is also important that it should not be buried below ground water level, in which case decomposition would be greatly retarded. To prevent putrefactive odor and the propagation of flies garbage should be kept as dry as possible. To prevent dissemination of germs by the wind it should not be dry if exposed. Exposure to the weather is, therefore, in any case objectionable.

The trench is usually about 3' wide and 12" deep. The garbage is spread in 6" layers and immediately covered with 6" of earth. For winter use 10' or 15' of trench should be prepared in advance for each ton of garbage expected. Care should be taken in providing ample cover to prevent dogs, rats, etc., from getting at the garbage and scattering it about.

Disposal by burying in trenches is more sanitary and less liable to create a nuisance than dumping, while utilizing the fertilizing value of the garbage. When this method is employed for garbage the rubbish may be incinerated or used with ashes as fill, in which case all boxes and cartons should first be broken up.

IV. DUMPING AT SEA

The dumping of garbage at sea is carried out by some 6 or 8 English cities, by Victoria, B. C., and in this country by Oakland, Calif., Newport, R. I., and in part by New York. It is often the cheapest method for seaport towns favorably situated, but open to the objection that landward winds bring much of the floating material to shore, even from long distances, where it litters the beaches and injures them for bathing and other recreational purposes. For this reason this method was abandoned by the City of Seattle in 1904, whose garbage was dumped in Puget Sound; and in New York incineration is being substituted.

Ashes and other heavy refuse are commonly and satisfactorily disposed of by dumping at sea, subject to federal control, but unless crates, laths and other light materials are carefully separated and removed, there remains an unsightly residue on the surface that is liable to litter up the beaches.

V. INCINERATION

Incineration provides one of the most sanitary methods of refuse disposal, if the incinerators are properly designed, constructed and maintained. There has

* In a recent case, officially reported, "the result is that residents in the vicinity of the stream deposit all household garbage as well as every other kind of rubbish and waste . . . in its channel. During the warm months of the year it is a shocking spectacle and it is alleged the odor at times is so bad that residents have to leave their houses."

"An official of one community, through which runs one of our finest rivers, very frankly stated to a representative of the Commission that the customary method of garbage disposal was to empty the garbage cans at night from the bridge over the river."—*1st Bien. Rep.*, Conn. State Water Com., 1925-1926.

been a noticeable trend toward incineration during the past few years which should result in the gradual reduction of offensive refuse dumps on the outskirts of cities and villages. The movement started by many villages to construct an incinerator on a coöperative plan is to be encouraged.

One of the most important factors to be considered in connection with the establishment of an incinerator, from an economic as well as from a sanitary standpoint, is its location. Since incineration is rarely a revenue producing means of disposal, the location of the incinerator near the center of the garbage production area is desirable, to offset the economical advantages of other systems. The site selected should not be in a residential section, or where a nuisance will be caused by the congregation of vehicles and apparatus in the vicinity. The incineration plant should not be located in a ravine, where the hills above the plant are built up with residences; for it has been found that where homes are at practically the same elevation as the top of the stack of the plant, at times nuisances may be created by odors before dispersion into the atmosphere can take place. This is particularly true at times when the incinerator is being put in operation.

It is of the utmost importance that careful attention be given to the design and construction of the incinerator itself. Owing to the strong competition among manufacturers, important parts in the design which are necessary for proper operation from a sanitary standpoint, may be omitted in order to compete with manufacturers selling an inferior product. Often a real reason behind this may be loosely written specifications. Attention is called to a report of this committee for the year 1925.¹ Among the most essential features which should be considered for sanitary reasons are a combustion chamber of suitable size and arrangements to facilitate combustion and arrest dust; provision of sufficient pre-heated air with forced draft to maintain high temperatures; and a sufficiently high stack to carry off and disperse the products of combustion.

The operation of the plant is most important. No matter how well the plant may be designed and constructed, unless it is carefully operated and maintained, nuisances may result. The charging chambers should not be overloaded; in other words, the plant should be sufficiently large to allow for flexibility of operation. A minimum combustion chamber temperature of 1,250° F. should be maintained, and the average should be 1,400° F., or even higher for some types of plants, in order to give complete combustion. This is essential to the prevention of objectionable odors.

The addition of fuel to garbage, if required to effect combustion, is one of the drawbacks of the incineration method. If sufficient rubbish can be collected, it may not be necessary to add other fuel. A mixture of at least 35 per cent of rubbish by weight with 65 per cent of garbage is usually necessary to insure proper burning. At one of the large cities in the central part of New York State, waste crank-case oil is collected in drums and used in the furnaces when large quantities of waste vegetables, such as celery and cabbage, are received in truck loads from wholesale merchants. This has been found very useful at such times and it also serves to keep this objectionable oil out of the public sewer system.

The incineration plant and its surroundings should be maintained in a sanitary condition at all times. The garbage should be handled as rapidly and as uniformly as possible so that no large accumulations exist. This will prevent nuisances from odors as well as from flies. No dirty vehicles nor apparatus should be left around the plant and the floors and walls of the building should be kept clean.

VI. HOG FEEDING

Hog feeding has the advantages of utilizing the food value of garbage, and of potential profit from the sale of pork. A large initial investment is necessary, however, and there is danger of heavy loss from sickness in the herds. Unless rigidly controlled this method is subject to nuisance. It provides disposal for garbage only, ashes and rubbish being taken care of as before described.

Piggeries should be maintained only in places very remote from habitations even when properly supervised and with every precaution to prevent a nuisance. The hog houses or shelters should be cleaned daily and the cleanings disposed of in a sanitary manner, such as by burial or by plowing into the ground as fertilizer. The residue from hog feeding often amounts to about half the weight of the garbage. Attempts to produce fertilizer of the residue by drying and grinding have only been partially successful.

At least 100 hogs are necessary to dispose of 1 ton of garbage per day.

There are two methods of feeding: upon platforms and upon the ground. If platforms are provided, they should be of concrete. These are preferably enclosed in a building, thereby preventing the spread of odor and providing shelter in winter. The uneaten garbage should be hauled and buried and the platforms cleaned daily. Hogs should be fed upon the ground only where a large area is available so that the place of feeding may be changed often. The top soil should be plowed under frequently. Manure and other residue should be removed at regular intervals and the yards kept in as sanitary a condition as possible. It has been found difficult to maintain large piggeries without creating serious nuisance, except in the most remote places.

To avoid losses from death all hogs on arrival should be immunized against hog cholera. The garbage fed to them should be fresh, and care should be taken to eliminate razor blades, victrola needles and broken glass. Even with care losses from such things will probably amount to from 3 to 5 per cent annually. Hogs will consume from 12 to 30 (average 20) lb. of garbage and take on an average weight of 1 lb. per day each, or about 40 lb. per ton of garbage. To keep down the nuisance of flies a mixture of 4 lb. cresol, 4 lb. oil of Myrbane in 48 gal. of stove distillate, sprayed twice a day (being careful to avoid spraying the hogs themselves), has been found efficacious.

There seems to be no foundation for the common belief that garbage fed pork is less wholesome than grain fed pork. "With proper management the meat produced is equal to and cannot be distinguished from grain fed hogs."² It is true, however, that the grain fed hog increases somewhat more rapidly in weight.

VII. REDUCTION

As in the case of hog feeding, reduction and fermentation processes are applicable to garbage only, which should therefore not be wrapped at the source.

Reduction processes possess merit in the conservation of the grease and the fertilizer ingredients as separate merchantable products. Methods vary in detail, but as generally carried out the garbage is cooked in a digester by steam, freeing the grease with or without a solvent, such as naphtha, and then the residue, known as tankage, is pressed. The drainage or "stick liquor" flows to a tank where the grease is skimmed off and any grease left in the tankage is removed by percolating with solvent and recovered. The tankage is then ground as fertilizer. The stick liquor is sometimes used to enrich the tankage but whatever is discharged is highly putrescible and requires ample dilution.

Owing to the fluctuation of market prices for grease and tankage the revenue cannot be closely predicted. With large, well-conducted plants a profit may be realized, but with the prices that have held since the war a net revenue has been exceptional. For this reason and the fact that reduction plants are expensive to construct and maintain and generally result in a greater cost for haul than incinerators (as they are most economically operated in large units), and also because they are more liable to nuisance, few plants have been built in recent years.

The greater probability of nuisance is due to drainage of the stored raw garbage and in general to the greater difficulty in keeping the plant clean, but especially to the liability of offensive gases to escape during processes of percolation and drying, and from leaky pipes and fixtures. The waste liquor too is apt to contain more or less offensive putrescible material mixed or combined with solvent, setting free obnoxious odors that have been discerned at a distance of 8 miles. So far as possible, however, the solvent is recovered and used over again.

In the best modern plants, where no solvent is circulated in a closed system, and with care in operation, these odors can be controlled, and the plant may be centrally located without offense.

Reduction plants require careful supervision, and revenue should be of secondary consideration. For this reason they should be operated by the municipality. They are generally not to be recommended for towns of less than 80,000 inhabitants.

VIII. FERMENTATION

The fermentation of garbage, developed in Italy as the Beccari System, has the advantage of requiring a minimum of mechanical equipment and attendance. It appears to have been very successful in some of the larger Italian cities, but with the different quality of American garbage certain modifications appear to be desirable to reduce the moisture and to promote decomposition with freedom from odor. Experience in America is too limited to specify details, but it appears entirely practicable to obtain a fairly dry, innocuous product within 40 days' decomposition by providing ample aeration in the cell and by the addition of about 30 lb. calcium oxide and 1 lb. ammonium sulphate per ton of raw garbage. The weight of the humus produced is about 12 per cent of that of the raw garbage, and, after a few hours' air-drying, can be ground and sold as fertilizer.

By this program, odors which were formerly found objectionable on drawing the charge are avoided.

The process has the merit of conserving the fertilizing properties of garbage, freedom from odor, elimination of harmful bacteria (by the heat evolved), and of inexpensive construction and operation. On the other hand the space required renders it less favorable for large cities with high land values than for suburban communities and small towns.

IX. SUMMARY OF CONCLUSIONS

House Preparation

1. Refuse should receive the proper degree of separation.
2. Garbage should be drained. If it is to be incinerated, it may be wrapped.
3. Receptacles should be of metal, water-tight and fly-proof. They should be kept covered, placed at the properly designated point of collection and cleaned to prevent odor.
4. Cans, metal and glass may be placed with the ashes in metal cans, but

paper should be excluded. If not too bulky, paper, cans and metals without sharp edges may be collected in stout bags of canvas or burlap. Mixed refuse should be treated as provided for garbage; but if without garbage, it should be treated as provided for ashes.

Transportation

1. Any scheme of collection should be correlated to the length of haul, the method of disposal and whether refuse is combined or separate.

2. Garbage and inflammable refuse may be mixed if disposal is by incineration; otherwise separate collection is preferred.

3. Unless contractual conditions are carefully drawn municipal collection and disposal is desirable.

4. Wagons or trucks and containers should be of metal and washed or disinfected daily.

5. The bodies of wagons or trucks should be hung as low as practicable for convenience, and provided with covers.

Disposal on Land

1. Ashes, metals, glass and crockery may be dumped on land, but paper, boxes, etc., should be separated out and all fires extinguished.

2. Dumps of mixed refuse, where necessary, should be made with garbage at the bottom, ashes on top and the exposed surface promptly covered with at least 4" of earth.

3. Dumps should be located at remote points and not along the banks of watercourses.

4. Garbage may be buried in trenches 12" deep to a depth of 6" and covered with at least 6" of earth.

Dumping at Sea

This is a satisfactory method of disposal for ashes and other heavy material provided that all wood and other nonsinkable material is carefully excluded, but it is not desirable for garbage.

Incineration

1. The incinerator should be placed in an industrial location but not in a ravine, where the gases of combustion might reach habitations.

2. To avoid the use of fuel the charge should consist of at least 35 per cent rubbish by weight with 65 per cent garbage.

3. Combustion chamber temperatures should be maintained above 1,250° F., and average at least 1,400° F.

4. The plant and its surroundings should be kept in a clean condition.

Hog Feeding

1. Piggeries should be located at a distance from habitations.

2. The hog houses, grounds and feeding platforms should be kept clean and all refuse promptly removed and plowed under or buried. Feeding platforms should, if possible, be enclosed.

3. Garbage fed to hogs should be free from injurious substances and in a fresh condition.

4. All hogs should be inoculated on arrival for hog cholera.

5. Flies should be kept from breeding by the application of suitable chemicals as a spray or otherwise.

Reduction

1. The raw garbage should be drained but not held in storage long enough to putresce.
2. The solvent or drainage liquors containing solvent mixed with organic matter should not come in contact with the outside air.
3. Reduction plants require intelligent supervision. Care should be taken to keep the plant in a clean condition and to repair all leaks and other defects without delay.
4. Reduction plants should only be considered in the case of large cities.

Fermentation

1. Fermentation plants require careful design, and intelligence in operation.
2. Fermentation plants may prove, with further experience, adapted to suburban or rural communities, where land is not too costly and where a local market for the product as fertilizer can be assured; but as yet they must be considered as in the experimental stage.

Argentina League of Mental Hygiene

THE Argentinian League of Mental Hygiene was established in Buenos Aires on December 6, 1929, through the influence of the Society of Neurology and Psychiatry. The League will study and put in practice means for the prevention of mental disorders. It will work for the application of mental hygiene in schools, industrial establishments, and other places, and for the improvement of the methods of treating mentally ill persons. It is hoped that these aims will be realized through the organizing of congresses and conferences and the enlisting of the cooperation of the public authorities.—*Semana Med.*, Buenos Aires, Jan. 30, 1930, p. 320.

SERUM TREATMENT OF MENINGITIS

THE use of antimeningococcic serum for the treatment of cerebro-spinal meningitis is an accepted procedure, the usefulness of which is generally admitted. There are, however, rumors and even published reports that antimeningococcic serum is not accomplishing all that might be desired. In the epidemic reported by Anderson two of the serums employed (one of which was produced by a state laboratory) appeared to be of definitely more value than others which should have been of equal excellence. This should not imply laxity on the part of any or all of the commercial manufacturers but is, rather, a reflection on our lack of adequate laboratory methods for determining in advance the therapeutic activity of these serums.

Determination of the potency of antimeningococcic serum is now based almost entirely on its content in agglutinins (or complement-fixing antibodies) for certain type strains. This method is preferred to others largely because of its simplicity and because the results obtained with it can be readily repeated. Other methods, some of which involve the use of animals, have been suggested but are not widely employed. There is, in truth, no reliable method at present available. To quote Dr. McCoy, "There is hardly any more unsatisfactory standardization in connection with biological products than the present-day standardization of antimeningococcus serum."

One point of value in treating meningitis cases is that a patient who is doing poorly under treatment with one batch of serum may improve under treatment with another batch. It is not always necessary to obtain the product of a different manufacturer, for it will

sometimes happen that, of two lots made by the same manufacturer, one will be more efficacious than the other, in an individual case. Better results may be obtained if the infecting organism is isolated and tested for agglutinability by samples of several batches of serum; and then treatment is continued with that lot of serum which gives the best agglutination. Some of the cases reported have been so rapidly fatal that no serum could be of any possible value. Cases dying within 24 hours of admission to hospital were almost certainly beyond the aid of serum therapy at the time they entered the hospital.

At the moment, meningitis may still be listed among those diseases deserving further study, particularly from the standpoint of serum therapy. It is reasonable to believe that a well equipped group could expect to improve present methods and suggest means which would restore this serum therapy to at least the level which it attained some years ago and from which it is thought to have receded within the past few years. At present there is danger of the development of a do-nothing attitude which may lead to the abandonment of a reputedly valuable agent.

HEALTH COUNCILS

SYMPATHETIC coöperation of a constructive and preventive nature has become recognized as essential if community health and welfare organizations are to serve the public most effectively. As the public health program has broadened with the introduction of new lines of service and the emphasis on education in the principles of hygienic living, consideration has naturally been given to the relative values of different health activities. The Health Council plan has developed to meet the local needs for a coördinating and supporting voluntary body of representative public spirited citizens.

The Health Council is usually made up of a lay person and the executive of each private health agency, representatives of public health organizations, and members-at-large. This group constitutes the governing body.

The purposes of the Health Council are primarily as follows:

1. To promote the coördination of public and private health work.
2. To serve as a forum for the discussion of health and sickness problems, policies, and plans.
3. To develop new and to improve present standards of service through joint study of special problems.
4. To secure improvement of existing health facilities and services and the establishment of new or additional health facilities or services where needed.

5. To give moral support to the existing department of health, in coöperation with the local dental and medical societies.

The Cincinnati Public Health Federation was the first city Health Council organized. Such councils are now active in Allegheny County, Boston, Cincinnati, Cleveland, Denver, Louisville, Minneapolis, New Haven, San Francisco and Syracuse. Groups usually connected with a Council of Social Agencies or a Community Chest exist in some 20 cities for the purpose of rendering services somewhat similar to those of the 10 Health Councils. Massachusetts is the only state council formed. The National Health Council, established in 1920, included in its membership 15 national health agencies. It has recently been reorganized as primarily a service organization for purchases, library maintenance, and similar functions.

A primary function of a Health Council is the development of better understanding between the official and private health agencies of a city. Through special studies by executives and committees, many community health problems are carefully analyzed. Child hygiene, health education, mental hygiene, social hygiene, convalescent care, chronic diseases, dental care, public health nursing, tuberculosis, and industrial hygiene are among the problems which have been considered during the past year in an effort to secure sound program planning. Several stimulating public addresses have been sponsored, and important publications have resulted.

SEWAGE AND CONSERVATION

TO a large proportion of our population, the thought of conservation in connection with sewage would seem preposterous, but to a small group, including health and municipal officials and a few industrialists, such is not the case. At the present time one of the problems in the sanitary engineering field receiving much thought and study is how to design a sewage treatment plant that will not only act as a device for innocuously caring for sewage but will at the same time produce some return even if it be more or less intangible.

Sewage farming, among the oldest of the sewage treatment processes, has a conservation phase to it but to a limited extent. The application of sewage to land not only in the negative light of using the land to dispose of the sewage but also in the positive way of utilizing the sewage to fertilize the land has been practiced for many years. In the sections of this country where water is scarce for agricultural purposes, the application of sewage to the land has served a useful purpose and has permitted the saving of other water more suitable for

higher uses. A recent statement indicates that in arid or semi-arid areas there is a decided tendency to turn further to land disposal.¹

Attempts to use as a fertilizer the sludge which results from the treatment of sewage, both in its natural form and artificially improved, have been numerous. Reports as to the value of untreated sludge as a fertilizer have been conflicting, probably due to the variation in the sludges used. By adjusting the chemical make-up of a sludge as is done at Milwaukee, Wis.,^{2, 3} it appears that greater success in its use as a fertilizer can be had. Although there may be no net income to a municipality in utilizing its sludge, such fertilizing value as it may have is not being completely lost.

The first attempt in this country to utilize gas from Imhoff tanks was at the Peachtree sewage treatment plant in Atlanta, Ga., 1915. Since that time this practice has spread widely. In most cases, collected gas is put to some useful work, as at Birmingham, England,⁴ and Charlotte, N. C., where it drives gas engines. Efforts are now being directed toward the stimulation of the digestion of sewage so as to produce more gas. This method of conserving an energy producer has merit and will probably go far.

The most recent attempts to get something useful out of sewage have been along the lines of reclamation. The cost of hauling fresh water into the Grand Canyon National Park⁵ was a major factor in bringing about a sewage treatment plant design which would produce an effluent suitable for reuse as boiler feed water. It is now reported⁶ that a large oil company will attempt to reclaim 6 million gallons of Los Angeles sewage for the same purpose, and that the city of Los Angeles has taken its first step toward the reclamation of some of its sewage to replenish the underground water supply and for industrial uses.

The health of the public benefits through the proper treatment of sewage and if this conservation viewpoint stimulates more sewage treatment, it is acting indirectly as a favorable factor in public health work.

Considered the most beautiful in the South*

THE HOST-CITY FOR 1930

IRA C. CHASE, M. D.

*Advisory Council of the Department of Public Health and Welfare,
and Vice Chairman, Citizens' Committee, Fort Worth, Tex.*

THE next meeting of the A. P. H. A. will convene in Fort Worth, Tex., October 27. You who attend will of course have first interest in the real Association work. When you step from the airplane or Pullman you may be interested to know that you are in a "Town that Jack Built"; that is, a one-generation town, conjured into existence by poor, energetic, virile empire builders. Think of a set of men who can in their lifetime transform a prairie into a city of 200,000 population, build its skyscrapers, pave its 86 miles of streets, erect its hotels and banks, its 57 schools for 35,000 children, 206 churches, 11 hospitals, 19 lines of railway outlet, lay out 43 parks, provide water and sewage systems, colleges, libraries, aviation fields, etc. Look at Fort Worth from this angle.

Fort Worth is about midway between the Atlantic and Pacific Oceans, 323 miles from the Gulf of Mexico, 717 miles south of St. Louis. Its elevation is

670 feet; climate is dry and mild, with a mean temperature of 65.2°; the heat of summer is modified at night by the monsoon winds drawn from the Gulf toward the heated, arid plains of the Northwest. It is one of the most healthful parts of the United States.

In the old days settlers first "fell on their knees and then on the aborigines"; churches and forts were of first importance. A modern settlement clusters about pure water, sewage disposal, health department and hospitals; schools, churches, courts and jails are secondary.

This "Town that Jack Built" is planned in a modern manner, and the result is that Fort Worth has the lowest death rate of the principal cities of the South and ranks third in cities of 100,000 or more in the United States. Great artificial lakes supply filtered and treated water. Extensive sewerage and disposal plants complete the system. A real American Public Health and Wel-

New Methodist Hospital, Fort Worth, Texas

St. Joseph's Hospital, Fort Worth, Texas

fare Department is a part of the City Government. Eleven hospitals provide care, one the most beautiful in the South, another of 400 beds unexcelled in the United States.

Here is the home of the State Medical Association of Texas, with its 3,800 members, and the headquarters of the *State Medical Journal*. Here is a County Medical Society of 180 physicians, all eager to make the meeting of the A. P. H. A. a success.

Within a few hours' ride is the

"Heart of the Cow Country," the Swenson ranches, where novelists prepare their material and artists get their poses and inspiration. Here is given the world's greatest rodeo annually. Here is the greatest oil-line center of the world, with 8 refineries, the greatest packing industry in the South, the greatest food distributing point and the largest manufacturing center of the Southwest. Take a look at a "Town that Jack Built." It is an inspiration to an American.

ASSOCIATION NEWS

MEETING OF EXECUTIVE BOARD

A MEETING of the Executive Board of the American Public Health Association was held on April 5 in the headquarters office, with all members of the Board present, together with the chairmen of three of the four standing committees.

Financial Report—The Board received the report of the financial condition of the Association at the end of the first quarter, which showed a total income of \$65,167.94, and a total expenditure of \$42,250.48, with all committees operating well within the budget allotments.

Section Appropriations—Upon the recommendation of the Finance Committee, the Board approved a budget of \$2,000 for expenditures of the sections, this sum to be drawn on by the several section secretaries in accordance with budgets submitted, and for items approved by the Treasurer and Executive Secretary. Authorized expenditures will cover postage, stenographic service, telegrams, long distance telephone calls, and similar expenditures of the secre-

taries for section business which cannot easily be provided by the administrative office.

Grant from Commonwealth Fund—Upon the recommendation of the Finance Committee the Board accepted a grant of \$3,000 from the Commonwealth Fund, to be used for the training of an additional field worker under the Committee on Administrative Practice.

Life Membership Fund—Upon the recommendation of the Finance Committee the Board established a Life Membership Fund to which are to be deposited directly all dues from Life Members, the income from the Fund to be paid into current income of the Association and the capital fund to be held for future disposition by the Board.

Constitution for the Western Branch—A tentative draft of a Constitution and By-laws of the Western Branch of the American Public Health Association was submitted to the Board. Several provisions of this Constitution and By-laws were approved in principal by the

Board, and the Secretary of the Western Branch and the Executive Secretary of the Association were instructed to prepare in consultation a final draft for approval by the Board and the Western Branch members at the meeting in Salt Lake City in June.

Committee on Meetings and Publications—The Board received the report of the Committee on Meetings and Publications which recommended that, following the Fort Worth meeting, there be arranged a trip to Mexico City in response to an invitation from the Chief of the Public Health Service of Mexico, and approved plans for this trip and a scientific program to be arranged in Mexico City.

The committee also reported on the activities of the Sub-committees on Annual Meeting Program and Syndicated Public Health Bulletin.

At the conclusion of his report, the chairman, Abel Wolman, tendered his resignation as chairman of the Committee, expressing his appreciation of the assistance of members of the Executive Board, his committee and the staff.

To succeed Mr. Wolman as Chairman of the Committee on Meetings and Publications, the Executive Board elected C. C. Young, D.P.H., of Lansing, Mich.

Committee on Fellowship and Membership—A report was received from the Committee on Fellowship and Membership outlining its activities in the promotion of sustaining and active membership. The committee announced the appointment of Carl E. Buck, Dr.P.H., as Chairman of the Sub-committee on Membership Promotion.

Committee on Administrative Practice—The report of the Committee on Administrative Practice, presented by Louis I. Dublin, Ph.D., announced completion of surveys and appraisals in Athens and Clarke County, Ga.,

Rutherford County, Gibson County, and Sullivan County, Tenn., and Washington, D. C. Arrangements have been completed for further surveys during 1930 in Memphis, Tenn., Kansas City, Mo., Fargo, N. D., and Marion County, Ore. The annual consultation service is to be extended as in the past to Detroit, Mich., Monmouth County and Newark, N. J., and Montreal, Canada.

The report indicated that the field work of the study of rural health work will probably be completed in November, and this will include detailed surveys of 50 county health organizations. The first analysis is expected to be completed about June 30, 1931.

The committee reported that 140 cities had been entered in the Health Conservation Contest of the U. S. Chamber of Commerce and, of this, 108 had returned completed schedules. These returns were carefully graded by the Grading Committee on April 4, and recommendations of this committee transmitted to the Board of Judges of the Chamber of Commerce of the United States. Eighty-seven of the cities entered in the contest have received consultant service from the Association.

The Sub-committee on Record Forms is negotiating for the printing of record forms approved by the committee.

The Sub-committee on the Evaluation of Administrative Practice is outlining a program of research and is considering the fields of diphtheria and scarlet fever control for its studies.

The special committee to revise the report on community health organization expects this revision will be completed before the Fort Worth meeting.

Committee on Research and Standards—Abel Wolman, Chairman of this Committee, reported that pending completion of the organization of the committee there was no work to report.

Upon the nomination of Mr. Wolman the following were elected members of

the Committee on Research and Standards:

W. H. Frost, M.D.
 Edwin O. Jordan, Ph.D.
 Haven Emerson, M.D.
 Isidore S. Falk, Ph.D.
 George W. Fuller
 Prof. Henry C. Sherman
 Edgar Sydenstricker
 William H. Park, M.D.
 Prof. C. E. Turner
 Thomas Parran, M.D.
 A. Parker Hitchens
 L. R. Thompson, M.D.

The chairman requested permission to defer appointment of the two additional members prescribed by the By-laws until such time as the committee has actually begun work, to permit the addition of other members representing the special fields of activity which may be entered.

Report of Secretary of Minneapolis Local Committee—The Board acknowledged receipt of the report and directed the Chairman of the Board to express to the Minneapolis Local Committee the appreciation of the Association for the suggestions for the improvement of future annual meetings.

Committee to Coöperate with the Director of the Census—The resignation of Dr. Chapin as Chairman of this committee was presented and accepted by the Board. Dr. Emerson was appointed Chairman, and George H. Van Buren was appointed to fill the vacancy.

Allocation of Committees—A special committee consisting of Dr. Emerson, Mr. Wolman, and Miss Jean, appointed to consider the allocation of Association

and section committees to the four standing committees of the Association, presented its report with a suggested plan of allocation, and this was accepted by the Board and will be brought to the attention of the sections and committees concerned.

Policy on Committee Appointments—Two important matters of policy were definitely decided by the Board, namely, that the staff members of the Association should not be considered to be ineligible for appointment to Association committees, and that those who are not members of the Association may under special circumstances be appointed to Association committees.

Requests for Endorsement—Several requests for endorsement were received by the Board from national and state organizations related to the field of public health, and the Executive Secretary was authorized to express to these organizations that it was not in accordance with the policy of the Association to give such endorsements.

Constitution—The Constitution of the Association adopted at the Minneapolis Annual Meeting was referred by the Governing Council to the Executive Board for editing as to legal terminology, and the edited Constitution was approved by the Executive Board. (This will be printed in an early issue of the JOURNAL.)

Report of Nominating Committee—Dr. Ferrell, the Chairman of the Nominating Committee, presented the report of the committee listing 25 nominees to be voted upon for membership in the Governing Council at Fort Worth.

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition

of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, providing such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes or a written ballot cast by the Fellows present and voting at the Annual Meeting in Fort Worth will be elected for the three-year term, 1930-1933.

Fred Adams, M.B., D.P.H., Health Officer, Windsor, Ontario, Medical Officer of Health

TENTATIVE PROGRAM—FIRST MEETING
WESTERN BRANCH
AMERICAN PUBLIC HEALTH ASSOCIATION
Hotel Utah, Salt Lake City, Utah
June 12, 13 and 14, 1930

Thursday, June 12

8:00 A.M.—Registration of delegates and visitors.

10:30 A.M.—Call to order by W. C. HASSLER, M.D., San Francisco, Calif., President Western Branch A. P. H. A.

1. Address of Welcome—HON. GEORGE H. DERN, Governor of Utah, Salt Lake City.

2. Response—W. C. HASSLER, M.D.

3. Report of Secretary—W. P. SHEPARD, M.D., San Francisco.

4. Announcements—T. B. BEATTY, M.D., State Health Officer of Utah, *Chairman*, Committee on Local Arrangements.

Address: (Subject to be Announced), LEE K. FRANKEL, PH.D., New York, N. Y.

Friday, June 13

9:00 A.M.—Symposium on Meningitis—Presiding: FREDERICK D. STRICKER, M.D., Portland, Ore.

1. Bacteriology and Serology of Meningococcus, E. C. DICKSON, M.D., San Francisco, Calif.
2. Epidemiology of Meningitis, KARL F. MEYER, M.D., San Francisco, Calif.
3. Source and Incidence of 1928 Western Outbreak, J. C. PERRY, M.D., San Francisco, Calif.
4. Oriental Importation, GEORGE PARRISH, M.D., Los Angeles, Calif. WILLIAM C. HASSLER, M.D., San Francisco, Calif. E. T. HANLEY, M.D., Seattle, Wash. C. P. BROWN, M.D., Victoria, B. C.
5. Intermountain Incidence, W. F. COGSWELL, M.D., Helena, Mont. B. B. JAFFA, M.D., Denver, Colo. WILLIAM CHRISTOPHERSON, M.D., Salt Lake City, Utah. T. B. BEATTY, M.D., Salt Lake City, Utah. F. W. ALMOND, M.D., Boise, Idaho.

Discussion opened by: A. J. CHESLEY, M.D., St. Paul, Minn.

2:00 P.M.—General Scientific Session—Presiding: WALTER M. DICKIE, M.D., Sacramento, Calif.

1. Rocky Mountain Spotted Fever, R. R. PARKER, M.D., Hamilton, Mont.

Discussion opened by: W. F. COGSWELL, M.D., Helena, Mont.

2. The Possibility of Controlling Ticks by Parasites, PROF. R. A. COOLEY, Bozeman, Mont.

Discussion opened by: W. J. BUTLER, M.D., Helena, Mont.

3. Public Health Training for Western Health Officers, J. C. GEIGER, M.D., San Francisco, Calif.

Discussion opened by: P. COVINGTON, M.D., Salt Lake City, Utah.

4. Results and Effectiveness of Recent A. P. H. A. Survey in Hawaii, F. E. TROTTER, M.D., Honolulu, Hawaii.
5. Relationship of Health Departments to Industrial Hygiene, C. O. SAPPINGTON, M.D., Chicago, Ill.

7:00 P.M.—Business Meeting—Presiding: W. C. HASSLER, M.D.

1. Report of Nominating Committee.
2. Election of Officers.
3. New Business.

8:00 P.M.—Public Meeting—Presiding: H. P. KIRTLEY, M.D., Salt Lake City, Utah.

Address—The White House Conference on Child Health and Protection, H. E. BARNARD, M.D., Washington, D. C.

Saturday, June 14

10:00 A.M.—Symposium on Sanitary Aspects of Proposed Boulder Dam—Presiding: R. J. STROUD, M.D., Phoenix, Ariz.

1. The Sanitary Engineering Aspect, PROF. LEON B. REYNOLDS, Stanford University, Calif.
2. The Immigration Aspect, FRED T. FOARO, M.D., Stockton, Calif.
3. Waste and Sewage Disposal Problem, HARRY HOMMON, San Francisco, Calif.
Discussion opened by: EDWARD E. HAMER, M.D., Carson City, Nev.

2:00 P.M.—School Health Program—Presiding: C. K. MACEY, Boise, Ida.

1. Western Health Education, SALLY LUCAS JEAN, Health Education Consultant, New York, N. Y.

Discussion opened by: AMY LYMAN, Women's Auxiliary, Church of Latter Day Saints, Salt Lake City, Utah.

2. Nutrition and Dental Caries—
Discussion opened by: HYRUM BERGSTROM, M.D., Salt Lake City, Utah.

3. Public Health Nursing in the West, ELIZABETH SOULE, Seattle, Wash.

4. How Shall We Attack the Problem of Preventive Dentistry? GUY S. MILLBURY, D.D.S., San Francisco, Calif.

Discussion opened by: HARRY B. TALHELM, M.D., Denver, Colo.
 7:00 P.M.—Annual Dinner—Presiding: W. C. HASSLER, M.D.
 1. Presidential Address—W. C. HASSLER, M.D.

2. Installation of New Officers.
3. Appointment Standing Committees.
4. Report of Resolutions Committee.
5. Address—A. J. CHESLEY, M.D.
6. Adjournment.

COMMITTEE ON ANNUAL MEETING PROGRAM

THE second meeting of the Committee on Annual Meeting Program was held on Friday, April 4, with 18 people present including Section Secretaries. Mr. Eggert reported on behalf of the Fort Worth Committee on Local Arrangements. He said that the committee has been successful in concentrating most of the meetings in the headquarters hotel. He stated that all of the commercial and educational exhibits would be held in the Hotel Texas also. A number of inspection trips of interest to the delegates have been planned. Some of these mentioned were: Swift and Armour Packing Plants, Sewage Disposal Plant, Water Purification Plants, Municipal Air Ports, Hospitals, Child Health Centers, Tour of North Side of Lake Worth, Tour of City, Trip to Local Health Department, Tea at Women's Club, Tea at Golf Course, Drive, and Theatre Party.

Mr. Eggert read a letter from Dr. Rafael Silva, Director General, Departamento Salubridad Publica, Mexico, D. F., appointing 5 official delegates from his department to the meeting, not including himself. These delegates will present papers (subjects to be announced later) in the following sections:

- Dr. Salvador Bermudez: Health Officers and Epidemiology
- Dr. Manuel Martinez Baez: Public Health Education and Vital Statistics
- Dr. Pedro Perez Grovas: Laboratory and Food, Drugs and Nutrition
- Dr. Mario Torroella: Child Hygiene and Public Health Nursing

Joaquin M. Segura: Public Health Engineering and Industrial Hygiene

Mr. Eggert reported further on the proposed post-convention tour to Mexico City. The tour was recommended to the Executive Board for approval, and further details concerning the trip will be found on page 530 of this JOURNAL.

Section representatives reported for their sections. The Vital Statistics and Industrial Hygiene Sections requested that they be allowed four and three individual sessions respectively, instead of the two which had previously been allotted them.

The complete preliminary program will be published in the September issue of the JOURNAL.

It was announced that the Texas Association of Sanitarians, the State Conference of Sanitary Engineers, and the American Association of School Physicians are planning programs at the same time as the meeting of the American Public Health Association.

The committee voted to endorse the plan for arranging special trains from St. Louis to Fort Worth for those A. P. H. A. delegates who wish to take advantage of this convenience. Delegates will be requested to make their own arrangements for travel to St. Louis.

The usual convention rates will apply from all sections of the country to Fort Worth. Railroad rates will be published in the June JOURNAL with other information.

Pyramid of the Sun, Teotihuacán, Mexico

ANNOUNCING UNUSUAL 10-DAY POST-CONVENTION
TOUR TO MEXICO CITY FROM FORT WORTH!

PRELIMINARY plans have been approved by the Executive Board to extend the Fort Worth sessions to Mexico City with a joint program of scientific sessions, inspection, and entertainment, on the invitation of official Mexico.

A splendid 4-day program in Mexico City has been authorized by President Rubio and Dr. Silva and their respective staffs, which includes seeing the volcanic mountains, pyramids, and everything of interest in a city considered second most beautiful on this continent.

The trip to and from Mexico City will be made in a special train, visiting interesting and scenic points enroute such as San Antonio, Monterrey, the beautiful Mountains of Mexico and the Magic Valley of Texas, where citrus fruit grows the year around.

The train will consist of the very highest type of equipment, offering the luxuries of home, assuring those making

the trip every minute of delight from the time they leave Fort Worth until their return to their homes.

While the class of train will be as high as any entering Mexico, the cost will be much lower than has been offered heretofore in comparable service.

The program in Mexico City, and maximum service at minimum cost in transportation, are being planned; also, arrangements will be made for members of the Association to receive specially advantageous rates from their point of departure including the Mexico City tour and return.

The tour will be limited to members of the Association, their families, and friends. A communication will be sent shortly to every member, submitting a detailed itinerary and further information about the trip.

Reservations are necessarily limited and therefore early reservation is greatly to be desired.

NEW MEMBERS

Health Officers Section

Charles W. Bartlett, M.D., Tampa, Fla., City Health Officer
 Leo H. Flynn, M.D., Eau Claire, Wis., City Health Officer
 Russell E. Hobbs, B.S., M.D., Wichita, Kans., Director of Public Welfare
 Arthur McK. Shelamer, M.D., Union Springs, Ala., County Health Officer (Bullock)
 Roy B. Jenkins, M.D., D.P.H., Edmonton, Alta., Canada, Medical Officer of Health
 Joseph A. Preston, South Orange, N. J., Assistant Health Officer
 Herman O. Hodson, Hillsboro, O., Health Commissioner, Highland County
 D. R. Williams, M.D., Girard, O., Health Commissioner
 Ferdinand M. Ferguson, B.S., M.D., Las Vegas, Nev., County Health Officer
 Lester A. Round, Ph.D., Providence, R. I., Director of Public Health
 Joseph F. Woodworth, Banff, Alta., Canada, Sanitary Inspector, Rocky Mountains Park
 Loren Wallin, M.D., Natchez, Miss., Director, Adams County Health Department
 John T. McGarry, Lyndhurst, N. J., Sanitary Inspector, Board of Health
 Frederick T. Zieske, M.D., West Branch, Mich., Director, Consolidated Health Department, Dist. 2
 Harry A. Reese, M.D., Yuma, Ariz., City and County Health Officer
 Dr. Miguel E. Bustamente, Vera Cruz, Mex., Chief of Sanitary Unit
 Nelson E. Newbury, M.D., Cambridge, Mass., Student in Harvard School of Public Health, formerly Director of Health of Scranton, Pa.

Laboratory Section

Charles E. Holzer, M.D., Gallipolis, O., Owner of Holzer Hospital for private and public use
 Temp J. Worrell, D.V.M., Pampa, Tex., City Inspector
 William M. Groesbeck, Hornell, N. Y., Bacteriologist, Hornell Branch, Steuben County Laboratories
 Kenneth W. Riley, A.B., Grand Forks, N. D., Bacteriologist and Chemist, N. D. Public Health Laboratories
 Rosina R. Coulson, Arlington, N. J., Bacteriologist, formerly with State Department of Health, Boston, Mass.
 Lawrence J. Peterson, B.S., Boise, Ida., State Bacteriologist

Grace Eldering, B.A., Lansing, Mich., Bacteriologist, Michigan State Health Laboratory

Public Health Engineering Section

Marshall R. Diggs, A.B., Dallas, Tex., Vice-President and General Manager, Southwestern Sewer Company
 Sidney P. Armsby, B.S., Houston, Tex. (Assoc.)
 John A. Smith, Taylor, Tex. (Assoc.)
 E. W. Kelly, C.E., Duluth, Minn., Manager, Water Works
 L. Wesley Irwin, Los Angeles, Calif., Junior Civil Engineer, Department of Health
 Andrew J. Fuller, C.E., Youngstown, O., Sanitary Engineer
 Leonard M. Board, B.S., C.E., Morgantown, W. Va., Sanitary Engineer, Monongalia County Health Unit
 Alfonso Ysunza, Vera Cruz, Mex., Sanitary Engineer, Department of Health
 Eustace Keogh, C.E., Melbourne, C1 Aust. (Assoc.)

Industrial Hygiene Section

Stephen E. Whiting, B.S., Swampscott, Mass., Assistant Chief Engineer, Liberty Mutual Insurance Company

Food, Drugs and Nutrition Section

Paul E. Howe, Ph.D., Washington, D. C., Senior Biochemist charge of Nutrition Investigations, Animal Husbandry Div., U. S. Department of Agriculture
 Ruth Walker, B.S., Seattle, Wash. (Assoc.)
 John H. Bryant, H.D.A., Sydney, Aust. (Assoc.)
 Lillian B. Storms, Ph.D., Washington, D. C., Director, Home Economics Education Work, American Bottlers of Carbonated Beverages
 Herbert G. Bailey, Savannah, Ga., Chief Food and Veterinary Inspector, City Health Department

Child Hygiene Section

Allen M. Kerr, M.D., Pittsburgh, Pa., Medical Supervisor, Public Schools
 Dr. Massillon Saboia, Rio de Janeiro, Brazil, Medical Inspector of Public Schools (Assoc.)
 Ruth A. Bottomly, Philadelphia, Pa. (Assoc.)
 James W. Bruce, M.D., Louisville, Ky., Medical Advisor, Public Health Nursing Association
 Mary J. Baker, M.D., New Castle, Pa., Director of Health, Public Schools

Gladys O. Donaldson, R.N., Dixon, Calif.,
School Nurse, Dixon Union High School
District

Edwin A. Layton, M.D., Tacoma, Wash., Di-
rector of Health, Public Schools

Public Health Education Section

Nina B. Lamkin, New York, N. Y., Consult-
ant with Bellevue-Yorkville Health Dem-
onstration

Adolph J. Roth, Ann Arbor, Mich., Student,
formerly Director of Health and Physical
Education, Three Rivers, Mich.

Sister M. Sylvia Morgan, D.Sc., Scranton, Pa.
(Assoc.)

Francisco P. Miranda, Mexico City, Mex., Di-
rector of Hygiene Education, Department of
Health

Gertrude E. Cromwell, B.S., Aurora, N. Y.,
Instructor, Health Education, Wells College

Anna J. Main, P.H.N., Eureka, Kans., Health
Supervisor in Schools

Irving F. Barnes, M.D., Oyster Bay, N. Y.,
Public School Medical Supervisor

M. E. Burgess, M.D., Pine Ridge, S. D., U. S.
Indian Service

Theron A. Tompkins, B.S., Mt. Clemens,
Mich., Director, Health Education in Pub-
lic Schools

Edith R. Sappington, M.D., Corvallis, Ore.,
Assistant Professor of Hygiene and Public
Health, Oregon State College

David W. Pyle, Dallas, Tex. (Assoc.)

Public Health Nursing Section

Elizabeth Yerger, R.N., Elkton, Md., County
Nurse

Lela Price, R.N., Dover, O., Public Health
Nurse, Tuscarawas County

Virginia A. Jones, R.N., Richmond, Ind., Di-
rector of Public Health Nursing, Richmond
and Wayne Counties

Margaret H. Hand, Binghamton, N. Y.,
Broome County Tuberculosis Nurse

Gertrude F. Hosmer, B.S., Honokaa, Hawaii,
Public Health Nurse, Board of Health

Essie Bliss, R.N., New Lexington, O., County
Public Health Nurse

Netta Ford, York, Pa., Director, Visiting
Nurse Association

Elizabeth Burns, R.N., Wheaton, Minn.,
County Nurse (Traverse)

Edna L. Hamilton, R.N., Detroit, Mich., Di-
rector, Nursing Service, Children's Fund

Gertrude E. Brown, R.N., Pittsfield, Mass.,
Executive Secretary, Berkshire County Tu-
berculosis Association

Mary V. Anderson, R.N., Moorhead, Minn.,
School Nurse

Vivian C. Miller, Sacramento, Calif., School
Nurse

Ruth M. Miller, Sacramento, Calif., School
Nurse

Cecilia M. Giesing, R.N., Wausau, Wis., Mara-
thon County Nurse

Mrs. Abbie L. Wamsley, Kingman, Kan., Red
Cross Nurse

Epidemiology Section

J. Horace Gervais, M.D., D.P.H., Montreal,
Canada, Supt. of Contagious Disease Divi-
sion, Department of Health

Reginald P. Hardman, M.D., D.P.H., Toronto,
Ont., Assistant Epidemiologist, Department
of Health

Unaffiliated

Dr. Anna P. Boudin, New York, N. Y., Di-
rector, Dental Clinic, N. Y. Infirmary for
Women and Children

INTERNATIONAL HYGIENE CONGRESSES IN DRESDEN

ABOUT 100 members of the Asso-
ciation have joined the delegation
of the A. P. H. A. to the International
Hygiene Congresses in Dresden this
summer. They will sail June 14 on
the S.S. Adriatic.

They will attend the Congress of the
Royal Sanitary Institute in Margate,
England, June 25 to 28, and visit Lon-
don, Brussels, Cologne, Wiesbaden,
Vienna, Munich, Geneva, Lausanne and
Paris. The stay in Paris will be coin-
cident with The First International
Congress on Micro-biology.

In addition to the regular features of
the trip, special trips of scientific in-
terest are being arranged in the cities
visited.

Detailed information may be secured
from Homer N. Calver, Executive
Secretary, American Public Health As-
sociation, 370 Seventh Avenue, New
York, N. Y.

CORRECTION

WE are glad to correct a wrong
impression given by the news
item in the March issue concerning the
Washington, D. C., survey. The study
of hospital administration is being made
by A. C. Bachmeyer, M.D., superintend-
ent of the Cincinnati General Hospital,
assisted by Mary L. Hicks, executive
secretary of the Health Council of the
Louisville Community Chest. Neither
the American Hospital Association nor
the American Public Health Association
feels that such intimate studies can be
successfully carried on as an activity of
a professional society but that they are
better handled by an individual, and the
city of Washington is fortunate in hav-
ing so outstanding a person in the field
of hospital administration to advise its
local agencies on this matter.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Health Inventory of New York City—The Research Bureau of the Welfare Council has limited the scope of its study to questions relating to the volume of health service in New York City afforded by voluntary agencies and the relationship of the service rendered to the needs of the city. It has carried on its study in such a way as to parallel the inquiry made of the Health Department in 1926 by the American Public Health Association.

There are 300 agencies furnishing organized health services which are rendered either through clinics, home visits by the public health nurses, by health education or through institutions. The bed care of patients is not completely considered but rather does the study embrace the volume of service rendered through clinics, home visits and health education.

In 1926 it was shown that the New York City Health Department scored 63 per cent on the *Appraisal Form*. At this time complete data on the volume of service by unofficial agencies were not available. This additional information has been sought and the score raised to 70.9 per cent.

The health department maintains the majority of the infant welfare clinics in the city, 68 compared with the total of 37 furnished by all other agencies. Eighty per cent of the clinic attendance is at health department stations. For preschool hygiene the health department has provided no service. In the field of maternal hygiene the health department maintains 14 of the 91 available clinics. It furnishes a still

smaller proportion of clinic visits, but does provide 46 per cent of home visits in the field of maternal hygiene. Forty per cent of the tuberculosis clinics and about the same percentage of home visits are under the direction of the health department. Seven out of 141 clinics for venereal disease control are maintained by the department of health and receive 18 per cent of the total of 343,000 clinic visits.—*A Health Inventory of New York City*, Michael M. Davis and Mary C. Jarrett, Welfare Council of New York City.

School Health Service in New York City—Recommendations for the reorganization of the medical examination and health supervision of school children in New York City have been accepted by a committee consisting of representatives of the Department of Health, Department of Education and other health organizations.

Parents should appreciate that the prime responsibility for the health of their children rests in their hands. The plan of examination to be inaugurated in the schools is for those children who have not received the required examination from their own physicians. Those recommended for examination are: (a) all school applicants, before entering school; (b) all new children in kindergarten and first grades; (c) all in other elementary grades entering New York City schools for the first time; (d) all other children in elementary and junior high school grades found by teacher or nurse to have gross defects and those absent frequently on account of illness;

(e) all children in the 7th grade and those 13 years of age and above this age, who may be leaving school to enter industry; (f) all handicapped children to receive specialized examinations; (g) provision for reexamination and follow-up; (h) special examination for children entering competitive athletic sports.

The physical examinations are to be made by teams or groups consisting of 3 physicians, school nurses and clerks. Parents are to be invited to attend such examinations. Histories, testing of vision and hearing (except the entering grade), weights and measurements, are to be done in school prior to the medical examination. From the medical team one physician will be chosen to examine eyes, ears, vision and hearing; another heart, lungs and orthopedic condition; the third nose, throat, teeth, glands and skin. The record card is to be a combination of the scholastic and medical rating of the child.

The home follow-up for the correction of defects will be the responsibility of the school nurse. Children suspected of suffering from communicable disease will be visited by diagnosticians of the department. [This plan of the newly organized health service for school children in New York City is substantially identical with the plan which was developed and has been used so effectively in Detroit during the past 9 years.—Editor.] A Plan for the Medical Examination and Health Service of School Children of New York City, 1929—The Children's Welfare Federation, New York, N. Y.

Health Administration in Racine, Wis.—W. W. Bauer, M.D., Health Officer of Racine, has for the fifth consecutive year moulded his annual report around the *Appraisal Form for City Health Work* of the American Public Health Association. The department in 1929 rated 78.2 per cent, with a per-

fect score in vital statistics; 85 per cent in communicable disease control due to the failure of parents to avail themselves more extensively of diphtheria prevention and smallpox vaccination; 72 per cent for venereal disease control due largely to incomplete reporting; 96 per cent for tuberculosis control; 29 per cent for maternal hygiene due to the lack of prenatal clinic and field nursing service; 88 per cent for infant hygiene; 58 per cent for preschool hygiene (increased from 34 in 1928 due to special campaign); 87 per cent for school hygiene; 99 per cent for food and milk control; 89 per cent for sanitation; 96 per cent for public health instruction. Cancer control has also been included in the rating during the past 2 years and receives a credit of 43 for 1929. Heart disease control has increased to 74 per cent for 1929 as compared with 47 in 1927.

Racine has completed its fourth annual campaign for diphtheria eradication. In 1924 there were 121 cases of diphtheria reported and 5 deaths while in 1929 there were but 18 cases of which only 4 occurred in the last 8 months, and there were no deaths. The Health Officer states that his credit in the *Appraisal* for this work is low because the *Appraisal* does not consider the number of children to whom toxin-antitoxin has been given but only those shown to be immune by the Schick test. This annual report also announces the construction of a new City Hall in Racine, with appropriate quarters for the Health Department which have been designed by the Health Officer himself. —*Annual Report of Racine Health Department*, W. W. Bauer, M.D.

Epidemiological Studies in New Haven, Conn.—Dr. Dwight M. Lewis, Director, Bureau of Communicable Diseases, Department of Health, New Haven, has very kindly submitted a

sample of the epidemiological sheet which he uses to keep daily account of the incidence of certain communicable diseases in his city. The accompanying chart and key furnishes an idea of the sheet kept by the epidemiologist. New Haven has 33 wards but in order to save space the chart has been cut so as to show but 9 wards and 11 days of the month. A table at the bottom of the sheet carries a summary for the corresponding month for a series of years giving, as indicated by the key, cases of communicable disease and deaths from certain causes as well as total deaths. There also appears the number of deaths under 1 year of age and the deaths from pneumonia (lobar- or broncho-) together with age of the deceased. This work-sheet gives a very comprehensive picture of the current condition of the city's health.

C. C. YOUNG

AN IMPROVED TECHNIC IN BURRI'S METHOD OF ISOLATING OBLIGATELY ANAEROBIC BACTERIA

IVAN C. HALL, PH. D.

*Department of Bacteriology and Public Health,
University of Colorado School of Medicine and Hospitals,
Denver, Colo.*

IN 1902, Burri¹ devised the simple technic of a deep tube plugged at the lower end with a rubber stopper to facilitate the removal of a cylinder of agar containing colonies of anaerobic bacteria which he wished to isolate in pure cultures. These tubes, stated by him to be of the same dimensions usually used for bacterial cultures, were plugged with cotton at both ends for hot air sterilization; the rubber stoppers were

sterilized separately under water in a flask in the autoclave.

In making a culture, one of the cotton stoppers was removed and replaced with a rubber stopper. Three dilutions of the mixed culture in 2 per cent nutrient agar melted and cooled to 42° C. were then layered into the tube and covered with a further layer of sterile agar. After incubation the rubber stopper was removed and the agar cylinder pushed

out upon a piece of sterile filter paper, cut into thin sections 1-2 mm. thick with a flamed knife, and well separated colonies transferred as pure cultures to suitable mediums.

Burri pointed out the superiority of deep culture methods over surface methods of isolation, and more than ten years ago, after a fairly complete study of numerous devices for anaerobic culture,² I concluded that there were serious theoretical as well as practical objections to all surface methods of isolating obligate anaerobes,³ which caused me to adopt the Burri technic in a slightly modified form as the method of choice for isolating anaerobic bacteria. This has recently been described in detail.⁴

The most suitable size of tube is about 9 mm. x 180 mm. and instead of sterilizing the rubber (or cork) stoppers separately, they have been placed in position before sterilization. This required autoclave sterilization in the case of rubber stoppers, but there has always been considerable trouble both with rubber and cork stoppers becoming loose, even after they were reset when the culture was poured, permitting the melted agar to leak out before it congealed. This not only necessitated repetition of the work but was highly objectionable in the consequent contamination of the containers for the tubes and the work table, often with virulent and resistant spores.

Experiments were therefore begun several months ago to find a substitute for the stoppers, using first gelatin films hardened in formaldehyde, and later collodion films which it was thought might be stripped off when the cylinders were ready to be pushed out; but the gelatin films were an utter failure and the collodion films were clearly inferior to the stoppers.

Later, Capes-Viscose caps, now manufactured by the Dupont Cellophane Company, were tried. These caps are

sold in cans containing a weak solution of formaldehyde; they are therefore sterile. When placed over the end of a tube they contract on drying to form a tight fit. Unless they are soaked for a while in a glycerine solution, they become too dry in the arid climate of Denver and often crack. We experimented with various concentrations of glycerine and found that 5 per cent glycerine solution, sterilized in the autoclave, gave the best results; higher concentrations caused the caps to wrinkle. Burri tubes capped in this manner could be sterilized either in the hot air sterilizer (70° C. for one hour) or the autoclave (20 lbs. for 30 min.) but there was considerable cracking of the caps afterward, especially when they were sterilized in the hot air. They were scarcely satisfactory as a substitute for the stoppers; if a slight wrinkle was present the liquefied agar would run out, and the contact of the agar gel with the caps softened them and favored the growth of molds. We used them for a few weeks but only with indifferent success.

The idea then occurred to utilize the caps to hold the stoppers in and this gives us well nigh perfect performance either with rubber or cork stoppers. We prefer the latter as they are cheaper and permit dry air sterilization. The tubes are prepared by the technicians, cotton stoppered at one end, cork stoppered at the other, and sterilized. The cork stoppers are then reset, capped with moist cellophane caps that have been soaked overnight in sterile 5 per cent glycerine, and dried. Our technic differs again from that of Burri in that we do not layer different dilutions in the same tube; we prefer to tube the different dilutions separately and the sterile agar top layer seems entirely unnecessary. We also use 1 per cent agar instead of 2 per cent.

We practically never have leaks any more. No molds grow on the dry caps

and the stoppers and ends of the tubes are well protected against contaminations.

The cultures are opened by stripping the caps diagonally with a penknife and removing the stoppers by means of flamed forceps. If necessary, a little flaming of the tubes will cause the meat infusion 1 per cent agar cylinders to slide out into sterile Petri dishes and they may then be sliced or broken up

and seared with a hot spatula for the picking of selected colonies.

INOCULATING NEEDLES

E. G. HASTINGS

Professor of Agricultural Bacteriology, University of Wisconsin, Madison, Wis.

IN the February number of the JOURNAL, Dr. Mudge has described an inoculating needle which he has found to be advantageous over the glass handled needle or the devices to be obtained from various supply houses.

The needle handle used in our laboratories is made from No. 6 B. & S. gauge aluminum alloy rod, which can be purchased from the Aluminum Company of America. The rod is tempered so that it is sufficiently stiff for all bacteriological work. It can be obtained in pieces from 6' to 8' long, which can be sawed into pieces of convenient length with a hack saw. The rod supplies a perfectly straight handle.

The pieces of the rod are clamped in a vise and a groove sawed at a sharp angle to the axis of the rod. The depth of the groove at the end of the rod would be approximately one-half its diameter and would extend back on the shaft of the rod approximately 1".

Platinum iridium wire can then be placed in the groove, which is closed by gently tapping with a hammer. For student work, nichrome wire of No. 24 gauge is used in place of platinum iridium. The stiffness of nichrome wire is sufficient that a much smaller gauge can be used than is possible with the platinum iridium wire, the only disadvantage being that it heats and cools somewhat more slowly than the platinum wire. For continuous work the metal handle becomes uncomfortably hot.

A glass mantle for the lower handle can be made from ordinary glass tubing of approximately the same internal diameter as the diameter of the rod. The glass is closed at one end by fusing. A little sealing wax is placed in the tube, melted, and the aluminum rod inserted into the melted sealing wax, thus preventing the rod from dropping out of the glass.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Influence of Nonresident Deaths on Boston's Death Rate—The large number of nonresident deaths in Boston, 2,187, a total greater than that of any other American city having a population of more than 300,000, causes Boston's statistics to suffer by comparison with those of other cities. When it is considered that practically 19 per cent of the total deaths in Boston for the year 1928 were those of nonresidents, and that of these 91.5 per cent were deaths in hospitals, the importance of these deaths becomes apparent in the rate. The outstanding reductions are found in anterior poliomyelitis, which showed a rate of 1.75 per 100,000 against 0.50 when nonresidents were deducted; scarlet fever 3.88 against 1.88; diphtheria 7.88 against 4.13; cancer 153.52 against 115.74; and heart disease 306.43 against 277.15. Other diseases showing reductions in rate when our nonresident deaths were deducted are broncho-pneumonia, diarrhea and enteritis under 2 years, congenital malformations and accidents.

A striking feature is exhibited in a comparison of Boston's nonresident deaths with those of New York City. With a population more than seven and one-half times as great as Boston, New York City had only 2,050 nonresident deaths during 1928, or 2.6 per cent of the total deaths for the year. Boston had 2,187 nonresident deaths, or 18.9 per cent of the total deaths for the year. Comparing nonresident infant deaths, New York City had 144, or 0.18 per cent, while Boston had 362, or 3.1 per cent of the total from all causes. In cities with a population of less than 300,000 where information is available,

Hartford, Conn., Salt Lake City, Utah, and Albany, N. Y., had higher percentages of nonresident deaths than Boston, the figures for the year 1928 being 28.3 per cent of the total deaths for Hartford; 23.3 per cent for Salt Lake City; and 21.2 per cent for Albany.—*Boston Month. Health Bull.*, 19: 9-11 (Jan.), 1930.

Maternal Mortality—The Royal Free Hospital has published a report on maternal mortality and an analysis of causes of death. About 90 per cent of patients were booked for admission from antenatal clinics, and at the most about 10 per cent were sent in as emergency cases. All cases of puerperal sepsis were completely isolated from the main block of wards. The report was based on maternal deaths which occurred during the 8-year period 1921 to 1929, and included both in-patients and district patients. The total number of antenatal attendances during this period was 49,047. Among cases in the hospital, there were 77 cases of placenta praevia, 21 cases of eclampsia, 10 cases of craniotomy, 476 cases of forceps, giving 5 per cent of all deliveries, and 152 cases of cesarean section, or 1.6 per cent of all deliveries.

There were 26 maternal deaths, corresponding to a mortality rate of 2.8 per 1,000 live births. The number of infants born alive was 9,152; neonatal deaths, 145; total number of stillbirths, 366, of which 199 were at term and 167 premature. Six deaths were attributed to obstetrical shock, 4 to shock from hemorrhage, 6 to sepsis, 2 to embolus, 4 to toxemia and eclampsia, 1 each to broncho-pneumonia and acute appendi-

citis. An equal number of deaths occurred among primiparae and multiparae. The primiparae preponderated only in the toxemia group. The cases of puerperal sepsis showed that operative interference and complications at labor increased the risk of sepsis to a great extent. Most cases of toxemia had some dental sepsis. Extraction and dental treatment were carried out in over 70 per cent of the patients treated in the antenatal clinics.—L. McIlroy and B. Turner, *Lancet*, 1: 97-99 (Jan. 11), 1930.

Age Distribution of Influenza Deaths in Cleveland, O., 1918-1929

—The marked differences which exist in the distribution of deaths registered as "influenza" by age, sex and color in pandemic and interepidemic years warranted the belief that there were fundamental differences in the etiology of the respiratory infections listed under that title. During the influenza epidemic of 1918, it was generally believed in Cleveland and elsewhere that the population groups hardest hit were those of middle life.

A study of mortality rates of influenza and pneumonia for the months of increased incidence from the pandemic in 1918 to the subsidence in 1928 was undertaken. The data were compiled from the records of the Division of Health of Cleveland. The curve for 1918 showed high mortality rates in middle life, which is characteristic of pandemic influenza. The striking difference between this and the curve for influenza of the years since 1918 was an almost certain indication that there was a difference in etiology. The pneumonia curve of 1918 with respect to the rates in advanced life corresponded to the normal pneumonia curve and to that of influenza in non-pandemic years but differed from these by a rise in the rates for the middle decades of life. The influenza curve of 1920 was very similar

to the pneumonia curve of 1918; however, this probably included both the influenza of non-pandemic years and true pandemic influenza. The distribution of deaths by age in the normal pneumonia year and in the influenza epidemic not of pandemic type was practically identical.

Comparing the Cleveland data for 1918 and subsequent years with those of the registration area from 1890 to 1918, there was complete agreement in age distribution and sex. As to the latter, 54 per cent of the total deaths during the 1918 epidemic were male deaths while in the so-called influenza of succeeding years 48 per cent were male deaths.

The estimate of Cleveland's colored population was too uncertain to warrant any comparison of white and colored deaths.—G. W. Moorehouse, *Am. J. Hyg.*, 1: 196-201 (Jan.), 1930.

The Problem of Diabetic Mortality—Within the past 15 years, the position of the diabetic patient has undergone a remarkable change. The dietetic treatment of the disease has been completely altered. Since 1922, insulin has been recognized as an essential method of treatment. With the use of this valuable therapeutic measure, a decrease in diabetic mortality was expected. But there has been slight alteration in the diabetes death rate within the past 6 years. Elliot Joslin was one of the first to recognize this as early as 1925.

An analysis was made of the diabetes mortality in the State of Victoria before the introduction of insulin and for subsequent years. Since the introduction of insulin therapy there has been a definite decrease in deaths in younger people up to age 45. This is not surprising because complications which play an important part in older patients are rare before the age of 40 and by control of the diabetic condition these younger people are allowed to live for many

years in comparative safety. There has been a distinct increase in diabetic mortality in the higher age groups. The increased mortality over age 50 has occurred largely among females. This has been noticed also in the United States and England but may be due to the disproportion in sex distribution accentuated as a result of the late war. The peak of the mortality curve has shifted from age 65 to 70. The average expectation of life has been increasing but not to an extent sufficient to explain such a marked shift.

There is definite evidence particularly in the statistics of other countries that diabetes waxes and wanes with the circumstances of the people. It is therefore conceivable that alterations in the habits of life of the people and the overtaxing of the parts of the body engaged in carbohydrate metabolism may be responsible in part for the increase in deaths which are classed as diabetic.

Another analysis was made of the diabetic mortality statistics in Alfred Hospital for the 4 years immediately prior to the use of insulin and for the 6 subsequent years. There has been a marked decrease in the deaths from uncomplicated diabetes but no change in complicated cases. The average age at death of the uncomplicated cases is 37 years while that for the complicated cases is 57 years.—Ewen Downie, *Victoria, Australia Quarterly Health Bull.*, 623: 629 (July-Sept.), 1929.

Prevention and Treatment of Pneumonia—The effect of concentrated serum on the death rate from pneumococcus pneumonia was shown in a summary of 885 cases observed in Bellevue Hospital. Altogether, 441 patients with pneumococcus pneumonia were included in the serum treated group. The most striking results were obtained in the pneumococcus Type I series. In 153 treated cases, the death rate was 20.6 per cent while the control

series of 147 cases showed a mortality of 32.6 per cent. For Type II, the mortality was 41.5 per cent for treated and 54.5 per cent for untreated. Serum did not have any effect in pneumococcus Type III cases, the death rate being actually higher for treated cases, 40.0 per cent as against 28.6 per cent for untreated. In the miscellaneous group IV cases, serum seemed to have a beneficial effect; however, factors other than serum may have modified the death rate from lobar pneumonia.

The death rate for the entire group of 441 treated cases was 30 per cent against 39.2 per cent in 444 untreated cases. Mortality for both series, treated and untreated, was lower in patients under 40 years of age than for patients over that age. Relatively speaking, serum appeared to be just as effective in middle-aged and elderly patients as it was in younger patients.

Treated patients admitted during the first 3 days of the disease had a considerably lower death rate than untreated patients admitted during the same period, in fact, distinctly lower than for the entire untreated series. This was most marked in the Type I group, in which the death rate for treated patients admitted early was approximately one-third of that for the entire group of untreated Type I cases. The death rate for Type II cases admitted early was 34.6 per cent against 54.6 per cent for the entire group of untreated Type II cases. Thus, if patients with Types I and II pneumonia were admitted early and treated with serum, the death rate for pneumonia, Types I and II, could be cut respectively to one-third and one-half the present figures.—R. L. Cecil, *New York State J. Med.*, 30: 210-214 (Feb. 15), 1930.

Health of Palestine—The Department of Health of Palestine reports a small decline in the infant mortality rate for 1928. The rate for the coun-

try as a whole is 186.34 per 1,000 and 203 per 1,000 among the Moslem population. The relatively low figure of 95.89 for the Jewish population is attributed partly to the interest in maternal and infant welfare and partly to the fact that Jewish mothers are comparatively young and healthy. The total birth rate of 53.98 compares with 50.35 in 1927, and the Moslem birth rate has risen to 60.99. The number of admissions to hospitals and attendance at dispensaries continues to be high. In general, services to pregnant women, infants and children among the Arab population are inadequate.

The department records with satisfaction that the standard of school medical service throughout the country has been well maintained. The health of the children both in Arab and Jewish schools is remarkably good, while the training in hygiene and the elements of mental science is having a beneficial influence on the pupils.—*Brit. M. J.*, 1: 81 (Jan.), 1930.

Public Health in Kenya—A 1928 health report for the Colony and Protectorate of Kenya stated that the most outstanding feature of the year in regard to incidence of communicable diseases was a number of severe outbreaks of malaria in the highlands. For a time, the situation was undoubtedly serious. No other unusual incidence of

communicable disease occurred during 1928 and it cannot be said that the general health of the Colony as a whole was less satisfactory than in previous years. Because of inaccurate vital statistics, any variations in health standards cannot be measured. However, work was begun in 1928 which will show its results later. This work was undertaken chiefly in connection with ankylostomiasis control in the Diga Reserve on the coast.

Findings to date showed the standard of health of Africans to be generally at a low level and the physique and capacity of the population to be affected as a result of infection with endemic preventable diseases. The incidence of plague was not notable. Five cases of smallpox were reported but the source of infection was not traced. Of acute fevers, pneumonia caused much sickness and was responsible for a high mortality. In native reserves, yaws caused much disability, 85,617 cases being treated during 1928. Syphilis presented a problem of some magnitude in certain areas. Increased efforts were made to induce patients to attend regularly for treatment.

Medical work in the Colony was carried out on normal lines. Particular attention was devoted to helminthic diseases and treatment of syphilis in native reserves and to malaria control in towns.—*Lancet*, 1: 113 (Jan. 11), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

A TYPHOID FEVER EPIDEMIC IN THE FAR NORTH

F. M. BRICKENDEN

*District Engineer, Canadian Department of Pensions and National Health,
Winnipeg, Man.*

AN epidemic of typhoid fever broke out at Mile 327 on the Hudson Bay Railway in Northern Manitoba, Canada, during the late winter and early spring of 1929. This epidemic included some 57 cases and about 8 deaths. A strict system of inoculation of all persons living in the area was enforced by the medical officers so that the epidemic was held in check and finally came under complete control by June, at which time the ice finally moved out of the lakes and rivers and summer conditions prevailed.

Mile 327 or Gillam is a diversion point on this railway, the water supply for which comes from a river not a mile away from the railway tracks through a system originally intended to supply the railway with water for its locomotives and general use.

A description of the location may assist this explanation. The railway, known as the Hudson Bay Railroad, has been under construction for some time. It runs from the Pas on the Saskatchewan River in Northern Manitoba, Canada, to Churchill, a port at tidewater on Hudson Bay, also in the province of Manitoba, about 59° north latitude. The distance between these two places is 511 miles. The country through which the road passes varies. The first few hundred miles is park country but the last section nearer the salt water goes through a muskeg, with only small timber growth parallel to the bay itself.

During construction many temporary arrangements were made to use the existing water supplies all along the line. In the case of Gillam, 327 miles away from the Pas, the water service originally installed to care for the locomotives and divisional shops only had as a source the little Nelson River.

This system consists of a pumping plant housed near the water's edge and equipped with a 30 H.P. Ruston-Hornsby fuel oil engine and a triplex pump, which takes water from a cylindrical deep well placed between the pump house and the river. There is but one pipe line from the pump to the standpipe and general outlet at the railway tracks. At this point, there is an elbow in the river which makes a sweep of about half a mile around to a point lower down where the outfall from the septic tank is located.

This outbreak appears to have been due to the fact that during the very cold winter weather the river was frozen solid below the outfall of the sewer, thus forming an ice dam in the river bed and gradually forcing pollution back up the stream and past the waterworks intake. The Resident Engineer had levels run following the freeze-up and found that there was no fall in the river, but that the water surface was level.

The original plan for this pumping plant was to supply engine water at the roundhouse only. Hence, when its use, unchlorinated, for drinking and culinary purposes became common, the

contamination immediately became apparent. There is a pedestal type of chlorinator in the pump house now which is in constant use.

The Department of National Health was called upon to check up on this outbreak and its representative arrived early in June. Several drastic improvements were recommended; as, for instance, the discontinuance of the practice in vogue at many of the pump houses on this line of returning waste water to the deep well.

The Munich Sewage Treatment Plant—The author describes some novelties in design and operation of the Munich sewage treatment plant, which is planned for a flow of 3.6 cu. m. per sec. The special features of the plant are:

1. Its use of large single units, which have proved to be more economical than a multiplication of small plants. Three years' experience has shown no ground water difficulties to be caused by the exceptional depth of the combined settling and septic tank.

2. The use of the rock of the district for most of the building, with reinforced concrete only for supporting parts, thin walls, and service bridges.

3. The special sloping angle of the tank walls, which has proved advantageous for sludge digestion as the sludge is deposited in the septic chamber in thin, even layers.

4. Underground drainage supplied with pump shafts so that tanks can be emptied without danger of floating.

5. The sewage is distributed by divided channels and unequal division of the sludge is remedied by screens in the main channel which break up accumulations.

6. The sludge is deposited on fields in summer as dry, and in winter as wet sludge. One-third of the available ground is covered yearly, and it is found that the process can be repeated after 3

years without harm as the sludge is practically consumed in that time. In discussing the utilization of the sludge as fertilizer, the author gives comparative analyses of Munich sludge, stable manure, and the dry Baltimore fertilizer, and an account of the most suitable crops and the methods and times of applying the sludge for different crops.

7. The plant is planned for simple and hygienic service. The amount of attention required by the different parts is described. No trouble is experienced with gas or sludge rising into the settling tank. The dredger which removes the dried sludge from the drying bed leaves a very thin layer of sludge on the sand. This prevents sand being deposited on the fields and also does away with the necessity for frequent renewal of the sand surface. The yearly service cost of the whole plant is about 0.13 RM. per head of the population.

8. Increase of income. This can only be done by the gas production. Experiments showed that gas production varied with temperature, that a completely de-gasified sludge dried badly, and that digestion was better in tanks covered for gas production than in uncovered tanks. The amount of organic matter per head of the population and the amount of gas per liter of organic matter were calculated and the results tested by laboratory experiment, which showed that 20.6 liters of gas per head per day could be obtained by complete digestion at a temperature of 26° C.

The part played by the floating layer of scum in the septic chamber is then discussed. At Munich this had to be removed after 21 years' working. The tank had to be put out of action for the purpose and gas production was low for some time after it was in action again. This was the result of the removal of an easily putrefiable layer just below the top layer of scum. A large septic chamber from which the scum

need seldom be removed is therefore an advantage. Another favorable influence on digestion is the direct current through the septic chamber. The method of calculating the amount of this current is described.

The harmlessness of the effluent is shown by the fact that even rainbow trout can live in ponds fed with it. The possibility of increasing the gas output by lengthening the period of digestion or by stirring or artificial heating is discussed.—H. Keppner, *Gesund. Ing.*, 52: 678-679, 1929. (From Papers of Water Pollution Research Board, England.)

Innovations in the Chemical Purification of Drinking Water and Information on the Present Application of Activated Carbon and Earth—A paper read at a meeting of the German Union of Gas and Water Experts, describing physical-chemical processes of purification, especially in connection with the supply to Magdeburg of Elbe water of very variable condition and composition. A list is given of over 50 methods of treatment on which a very large number of experiments on small and large scales were made. The Magdeburg plant for dealing with the river water is described and illustrated. The pumped river water flows through four filters at gradually decreasing speed. These are arranged in steps so that between filters the water is aerated by falling over a waterfall. Then follows sand filtration in covered primary filters, at four or five times the normal speed, and slow secondary filtration for bacterial purification. The different methods of cleaning these filters are described. Chlorine gas is added by OrNSTEIN'S process in the first pure water reservoir.

The author then deals with the experiments made to find the best means of using this plant. Chlorination of the raw water before the first filters was tried with liquid chlorine, and

with chlorine preparations such as Mianin and Duamin. This chlorination showed advantages in algae destruction, decrease of bacterial growth, and a longer filter period, but smell and taste were not removed.

Coagulants were then tested, using pulverized activated carbon as the adsorption medium. The history of the activation of carbon is given, and an account of experiments. Activated carbon, alum, and marble calcium hydroxide were added in this order before the primary filters. The adsorptive effect of the carbon was, however, impaired by the formation of a coating of aluminium hydroxide, though coagulation and physical improvement were good. The addition of activated carbon, lime and aluminium sulphate did not give good results. Alum, alone or with sulphuric acid, added either to the untreated water or before the primary filters, gave good results in iron and manganese removal, but smell and taste were not improved. Chlorination of the raw water with a subsequent addition of aluminium sulphate and lime showed that the chlorine brought into solution matter which should have been precipitated and that there was no saving of alum. It was found that there were two favorable pH points for precipitation, one from 5.2 to 5.5 and the other from 6.7 to 6.9.

More satisfactory results were obtained by treating the water before the primary filtration with filter-alum and fuller's earth, with subsequent activated carbon filtration. The final filtrate was satisfactory in freedom from color, taste, and smell; iron and manganese were absent and organic matter reduced to one-half. The application of this process to practice and the construction of an activated carbon filter plant are described. The results of the different experiments are given in tables.

In discussion, Link dealt with the present condition of the methods of

purifying surface water. Fuller's earth had not been found so satisfactory in Stuttgart. Activated carbon could be applied for the removal of excess chlorine. The process and construction of the filter required further investigation.

Adler mentioned previously used processes which corresponded to those examined by the author. The use of activated carbon was limited by its rapid saturation, and the lack of simple methods of regeneration. Its real application was as a dechlorinating medium.

Haupt confirmed that good results had been achieved at Magdeburg with fuller's earth. Settling time of sufficient length must be allowed. The purification of the water must be as complete as possible before the activated carbon filter is used to remove smell and taste.

Gruschka recommended the Adler process of superchlorination and dechlorination with activated carbon. This was satisfactory with phenol-containing waters.

Bamberg dealt with the problem of acidity in a piped supply and the difficulty of purifying Magdeburg water sufficiently for a satisfactory use of activated carbon.

The author in reply agreed that water should be well purified before the use of activated carbon, but pointed out that activated carbon was used with good effect on beet sugar factories' effluents. With the specially unfavorable and changeable Elbe water, fuller's earth, by its adsorptive capacity and specific gravity, shortened the settling time and lessened the cost of aluminium sulphate and of the carbon.

Bach emphasized the necessity of limiting the pollution in a river, so that a water suitable for drinking could be procured by treatment.—O. Koenig, *Gas- u. Wasserfach*, 72: 1065 and 1091, 1929. (From Papers of Water Pollution Research Board, England.)

The Anthrax Danger in Lahr and Its Removal—The problem of anthrax danger from hides and tanneries has not been satisfactorily solved. The author has investigated conditions at Lahr. The danger concerns men as well as animals and arises from the hides, not from the tanning waste water, though the latter encourages and increases it. To treat the matter at the source, infected skins should be separated. Disinfection of skins is opposed by the leather industry. The writer recommends further investigations by the State of the pickle-and-lye process and the Ascoli process. The use of solid wastes and residues as fertilizers should be forbidden, and the treatment plants kept under inspection to prevent solid matter being run off with the effluent. Inoculation of cattle, drainage of fields and improvement of cattlesheds should be attended to.—F. Uhlenhuth, *Reichsgesundsb.*, 4: 288, 1929; *Wass. u. Abwass.*, 26: 156, 1929. (From Papers of Water Pollution Research Board, England.)

Methyl Chloride Poisoning from Domestic Refrigerators—Toxic action of methyl chloride was first reported by Eulenberg in 1876. Pigeons were used in his experiments. Exposure to gas produced difficulty in breathing, dilation of pupils, and caused birds to stagger and fall. Removal from exposure was followed by prompt recovery.

Grabis was the first to report accidental poisoning from the gas in 1914. Roth, in 1923, reported 10 cases. Schwartz, in 1926, reported 10 cases and 1 death. In all the above cases, the gas came from ice machines. Baker, in 1927, reported 21 cases among employees in a factory manufacturing refrigerators. Since August, 1928, 29 cases in Chicago with 10 deaths have been reported.

The onset is generally marked by

progressive drowsiness, mental confusion, stupor, weakness, nausea, pain in the abdomen, and vomiting. The article gives an outline of the methods of diagnosis and treatment and also histories on 6 cases.—A. H. Kegel, W. D. McNally and A. S. Pope, *J. A. M. A.*, 93, 5: 353-358 (Aug. 3), 1929. Abstr. Paul S. Fox.

Some Examples of Pollution of Streams by Industrial Wastes—

Some of the forms of pollution are mentioned. Literature on the subject is listed and the question of legislation discussed. The Sudbury River in Massachusetts is taken as an example of a slightly polluted stream and the Pocasset River in Rhode Island as a grossly polluted stream due to wastes from textile establishments. The seasonal changes which the waters of these streams undergo are diagrammed and discussed. Remedies are suggested.

The author's conclusion states: The subject of industrial pollution is extremely important, not only for plants but for communities using the same streams. So far the data pertaining to the problem of purification of textile wastes are extremely limited, and it is hoped that increased appropriations may be placed in the hands of state authorities. Problems involving industrial sewage should be considered from the standpoint of the stream, and not from the standpoint of the individual plant. Group treatment is extremely desirable, and the formation of conservancy districts or river boards is to be recommended. Standards are difficult to establish, but it seems that an attempt should be made to maintain the dissolved oxygen at above 30 per cent, better above 50 per cent of saturation at all times. Not all textile wastes require purification, and great savings may be made by separating in the mill

the harmless wastes from those which should be purified. In some plants these latter amount to 75 per cent of the whole volume. Many streams require plain subsidence alone; others require treatment on filters. So far, single filtration has not been always effective, due to the antiseptic character of some of the wastes to be treated, or to the kinds of substances discharged.

While subsidence followed by double filtration has produced excellent results, the process is expensive, and it is unfortunate that the activated sludge process is not applicable to a waste with suspended solids of so low a specific gravity as that in certain textile wastes.—Robert Spurr Weston, *J. Boston Soc. Civil Engs.*, 16, 6: 358-373 (June), 1929. Abstr. L. W. Van Kleeck.

How Wilmington (Del.) Has Raised the Sanitary Standards of its Nine Swimming Pools—During the 1928 season excellent results were obtained in improving the condition of Wilmington's five municipal pools and four private pools by the use of a rating scheme based entirely on the chemical and bacteriological condition of the water. This method, however, had disadvantages such as excess chlorination, in pools of inferior construction, in an effort to secure a high weekly rating. As a result in 1929 the Board of Health adopted a score sheet based on the following items: equipment 100, management 200, water in pool 200.

Each section is subdivided and a perfect percentage allotted to the various items. The total score is divided by 5, giving 100 for a perfect score. It is claimed by the author that the system has been very successful in raising the swimming pool standard in Wilmington.—Russell T. Des Jardins, *Am. City*, 41, 2: 154-155 (Aug.), 1929. Abstr. J. B. Harrington.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

The Present Status of Industrial Medicine—The highest estate yet reached by industrial medicine was attained during 1917–1919. At this time (1929) stratification has occurred so that there are recognizable two large fields of related endeavors, “industrial hygiene” and “case handling industrial medicine.” The prime activity of the first of these has been numerous special investigations related to hazards, research, and constructive work in which unfortunately participation by organized medicine has frequently been missing so that at the present time there is a definite drift on the part of the industrial hygienist away from organized medicine, where he rightfully belongs. A lower non-medical stratum, not praiseworthy, has appeared, as exemplified by the optometrists who make extensive industrial surveys seeking patronage from the visually deficient. In an instance under the author’s observation, among 396 clerks wearing glasses, 60 per cent either obtained no visual betterment or vision did not reach 20/30.

“Case handling industrial medicine” embraces primarily routine care of the injured, minor physical relief, and physical examinations. Within this division there is much stratification, most of which is not industrial medicine or at least not good industrial medicine. There are recognized the following subdivisions:

The physician with a practice that includes industrial cases

The petty industrial emergency hospital, usually looking to the compensation boards for payment for services and doing capable

and often profitable work but seldom anything constructive within the factory

Dubious gratuitous services, hoping to profit through an increase in private work

Part-time medical services for small plants, a most important demand since 99 per cent of all plants are really small ones, i.e., employing less than 500, while in fact 49 per cent employ less than 6. (Often these efforts give praiseworthy service but practically may not function to the advantage of anyone since low salaries are paid, physicians are often not qualified, and a routine of minor emergency work is performed, as for example when a plant, perhaps even with 1,000 employees, seeks to meet its medical obligation through the services of a physician 1 hour daily.)

Full-time medical services with untrained personnel

Similar services with trained personnel which may or may not be permitted to practice real industrial medicine

Medical departments maintained by labor organizations such as painters’ unions—often a commendable endeavor though not industrial medicine

Medical service extended to entire families which is really community medicine

The objectives and standards of good industrial medicine, and the qualifications of physicians to perform the same, are next discussed in detail with an emphasis upon the fact that this is a specialty in medicine and that real industrial physicians are specialists and therefore need the offered extra form of university training and much experience. The few persons trained by institutions have readily found employment since industrial managers are recognizing the advantages of such training. There are listed 11 professional or official organizations and types of institutions now promoting industrial hygiene, and 13 administrative groups (not including health

departments) which are interested in the subject.

A "synthetic" manufacturer and a "synthetic" workman each give their respective views supporting the demand for industrial medicine (a very interesting summary).

Unfortunately, medical organization at present is so much in dread of "state medicine" that all extensions of industrial medicine, as, for example, to increase the lists of recognized occupational diseases, are opposed. This very lack of flexibility on the part of the medical profession may prove to be an outstanding factor in forcing on socialized medicine.

Let it be said that unlimited coverage for proved, characteristic, occupational diseases is coming. Its embracement may be expected by several additional states within the next six years. . . . Moreover, the medical profession should not lend itself to the jokers introduced into legislature to give the appearance of the extension of compensation coverages in lieu of embracing items of real significance.

In the entire field of industrial compensation there are outstanding drawbacks of special concern to the medical profession, e.g., there are few compensation boards with competent medical advisers, and claims are being settled by non-medical officials, grossly incompetent to pass on medical matters. Here, an alert medical profession may go far in the eradication of such sources of medical malactivity.

The author next lists 10 types of objectionable features of industrial medicine when conducted under undesirable conditions and 12 precepts which comprise a suggested attitude for organized medicine toward industrial medicine. (Five pages of discussion follow. The paper was read at the Annual Conference of Secretaries of Constituent State Medical Associations, held at Chicago, Nov. 15-16, 1929.)—Carey P. McCord, *A. M. A. Bull.*, 25, 1: 11-21 (Jan.), 1930.

Will the Inhalation of Siliceous Dusts Activate a Partially Healed Focus of Tuberculous Infection?—Experiments were made with 95 guinea pigs which were infected by inhalation with a low virulent strain of tubercle bacillus. Groups of animals were then exposed to inhalations of quartz, granite, or carborundum dusts for periods varying from 54 to 206 days. The concentrations of the dust in the chambers ranged from 640 million particles to 957 million particles per cu. ft. of air. Death of the animals generally occurred between 200 and 400 days after commencing the exposure but 2 of the carborundum animals survived to be killed on the 1,385th day.

The virulence of the tubercle bacillus used has been studied for about 12 years at the Saranac Laboratory. Quartz and carborundum dust have regularly caused the tubercular infection to become progressive in each animal exposed. Granite was much less active and no alteration was observed with marble dust or bituminous coal dust. In fact, the latter seemed to accelerate healing. Asbestos dust exerted a stimulating effect only in an occasional animal.

Quartz, granite, and carborundum dusts may reactivate and cause tubercles to spread which are as old as 200-400 days.

There was noted a high incidence of complicating pneumonia particularly in the granite group, which was caused by the Friedlander bacillus.

The character of the lesions produced by reactivation both in the undusted control animals and in those exposed to a prolonged inhalation of dust is described. Carborundum, which is the carbide of silicon, and which theoretically contains very little crystalline silica, is very active (in breaking down the tubercles). Apparently, quartz reaches the interior of the tubercle in

greatest quantity; next comes carborundum and the least amounts are granite dust.

The experiments have proved that in the guinea pig it is possible to light up a quiescent focus of tuberculosis and to render it progressive. However, this does not necessarily indicate that the same thing occurs in the human being, but the truth can be learned by careful clinical radiographic and post-mortem observations.—Leroy U. Gardner, Saranac Laboratory, *Pub. Health Rep.*, 45, 6: 282-288 (Feb. 7), 1930.

A New Journal in the Field—The *Archiv für Gewerbepathologie und Gewerbehygiene* appears for 1930, the first two monthly issues in a single volume, the publisher being Julius Springer, Berlin. The *Journal* is under the coöperative effort of the following: Charles Badham, Sidney; L. Carozzi, Geneva; B. Chajes, Berlin; L. Devoto, Milan; Cecil K. Drinker, Boston; H. Engel, Berlin; F. Flury, Würzburg; H. Fühner, Bonn; D. Glibert, Brussels; Leonard Greenburg, New Haven; M. Hahn, Berlin; K. Hamel, Berlin; Alice Hamilton, Boston; E. R. Hayhurst, Columbus; T. C. Houghten, Pittsburgh; M. Kaplun, Moscow; R. Kockel, Leipzig; F. Koelsch, Munich; Thomas Oliver, Newcastle Upon Tyne; D. Pometta, Lucerne; R. R. Sayers, Washington; M. Sternberg, Vienna; H. M. Vernon, Oxford; and C.-E. A. Winslow, New Haven, and under the editorship of Dr. L. Teleky, Düsseldorf, and Professor H. Zangger, Zürich.

The articles in the first volume include the following:

Introduction, Dr. H. Zangger, pp. 1-51 (in German)

Reflections on Certain Problems of Industrial Medicine, Prof. Dr. Luigi Carozzi, pp. 52-66 (in English)

Pulmonary Asbestosis, A Socio-medical Study, Sir Thomas Oliver, pp. 67-76 (in English)

Concerning Modern Organic Solvents, Heinrich Zangger, pp. 77-196 (in German)

Observations upon Arsenic Poisoning, Dr. Winfried Grassmann, pp. 197-202 (in German)

Climate and Work, Dr. Walter Strauss, pp. 203-239 (in German)

A Report upon the Question of Occupational Myopia, Dr. L. Teleky and Dr. Adolf Thier, pp. 240-270 (in German)

The Differential Diagnosis of Silicosis by X-ray Pictures and an Investigation of the Hazards in Sandblasters, Dr. Lochtkemper, with 18 illustrations, pp. 271-302 (in German)

The set-up of the *Journal* shows extreme care; the type is very legible; and the paper of fine quality, which carries the various illustrations and tables well. The price is 38.60 marks.—Julius Springer, Publisher, Berlin, W 9, Linkstr. 23/24.

Industry in Relation to Personal and Public Health—This is a very interesting historical discussion of the irregular improvement of the health of workers from prehistoric to present times. Probably silicosis is the oldest occupational disease, as it may be imagined to have existed among the flint implement makers in the prehistoric factories, such as those found at Grime's Graves near Brandon in Suffolk. Arguments are adduced to show that the great empires of the world have fallen one after the other, through the introduction of slave labor with the failure to protect the health of those employed.

It is recognized that industry is the instrument for preserving the health of nations. "In the sweat of thy face shalt thou eat bread" was in very truth a blessing and not a curse hurled at Adam. Intelligence cannot create industry without industry reacting and stimulating intelligence. Indeed industry may fairly be said to be the instrument used by nature for developing intelligence and preserving health.

The influences of climate, the introduction of water power, wind power, and of steam are reviewed, the latter in par-

ticular having at first led to the misuse of workers, but now labor saving devices are steadily eliminating poorly paid manual effort, while complicated processes are ever more and more being introduced into industry which call for specially skilled operatives. The future of the human race cannot be foreseen, but it will be determined by man's intelligence acting through his industries, until barren places of the earth are made fertile and come to support populations, kept healthy by physical and mental activities developed in the pursuit of well ordered industry.—E. L. Collis, *J. State Med.*, 37, 3: 125-137 (Mar.), 1930.

Some Facts about Pennsylvania Women Wage Earners—In a series of charts based on figures of the 1920 United States Census, with accompanying tables applying to the nearly three-quarters of a million women who are gainfully employed, or 1 out of every 5 women in the state, the Pennsylvania Bureau of Women and Children finds in brief as follows:

1. One-fifth of the employees of the state are women.
2. The percentage of women employed has increased from 10 in 1870 to 21 in 1920.
3. The percentage by occupations in 1920 was: domestic and personal service, 25; clerical occupations, 18; "other manufacturing occupations," 15; textiles, 12; professional service, 11; trade, 10; "other non-manufacturing occupations," 4; clothing, 4; and food, 1.
4. In seven cities, all located in the eastern half of the state, more than one-fourth of the women are gainfully employed.
5. Nearly one-half of the women employed are under 25 years of age, while less than one-fourth of the men are under 25 years of age.
6. Among women gainfully employed, 88 per cent are native born and 12 per cent foreign born.
7. Native born women of foreign or mixed parentage are more likely to be gainfully employed than either foreign born women or native women of native parentage.
8. Less than one-fifth of the gainfully employed women are married.
9. Practically one-half of the single, wid-

owed, and divorced women are gainfully employed; less than one-tenth of all married women are employed outside their homes.

10. Married women are more generally employed in domestic and personal service than in any other important occupational division. The highest proportion of single, widowed, and divorced women are employed in clerical occupations.

11. Only in domestic and personal service are more women employed than men. In manufacturing and mechanical industries in which one-third of the women of the state are employed, 16 per cent of the workers are women.

12. Next to household servants, the greatest number of Pennsylvania women are employed as textile operatives.

—Bureau of Women and Children, Dept. Labor & Industry, Commonwealth of Pennsylvania, Harrisburg, 1930, 23 pp.

Women in Trade Unions—A summary of a study of the German General Federation of Trade Unions emphasizes the increasing number of women workers in industry. In typical trades they have the following percentages according to the annual reports of the unions for 1928: tobacco workers 77.5; bookbinders 67.9; printers 64.1; hatters 63.3; textile workers 57.8; clothing workers 48.1; and shoemakers 44.3.

The percentage of women is likewise increasing in those unions in which their number is usually small, e.g., in the metal industry from 11.1 per cent in 1925 to 15.2 per cent in 1928, etc.

The unions provide a program of education for new workers, while the women are taking an important part in works councils. Owing to the continual influx of women in industry the wages of women workers are much lower than those of men, but considerable progress has been made in raising them.

In regard to maternity protection it is found that women are making increasing use of the right to leave work 6 weeks before confinement, but when engaged on piece work they are much less

willing to do so. However, under the decree of May 18, 1929, by which the allowance for the 4 weeks preceding confinement is increased to the equivalent of three-quarters of the basic wage, this condition is being bettered. There is often difficulty in carrying out the provisions relating to the 2 half-hour intervals for the nursing children. In some shoe factories the women have refused to take their infants to the nurseries provided because their clothing is saturated with chemicals. The Saxon Government has made extra monetary inducements to every pregnant woman to leave her work for 8 weeks preceding confinement.—*Indust. & Labour Inf.*, XXXIII, 7: 220-222 (Feb. 17), 1930.

Sugar—The per capita consumption of sugar in the United States in 1925 was 107 lb., compared with 8.8 lb. in the year 1823. The derivation of the sugar used in the United States according to Senate discussions shows as follows (percentages): Cuba (cane) 58.3; United States (beet) 15.39; Hawaii (cane) 10.89; Porto Rico (cane) 8.10; Philippines (cane) 5.51; and Louisiana and Texas (cane) 1.24. In 1929 it was estimated that 1,250,000 short tons of beet sugar were produced in the United States. Very little of the imported sugar is refined as received, so that it has to be re-melted and refined after reaching the country.

There are, then, in the United States 103 beet sugar factories, operating in 18 states, but especially concentrated in Colorado, Utah, Michigan, California and Idaho. There are also 60 "sugar-houses" in Louisiana and eastern Texas, grinding sugar cane but not producing the refined article, and 21 great sugar refineries located mostly at seaport cities. According to the Census of Manufactures for 1927, 79 beet sugar factories employed 8,872 workers, 53 cane sugar factories (not refining) 1,225

workers, while 21 cane sugar refineries had 15,742 employees. (The paper then takes up a detailed discussion of manufacturing processes with resulting health hazards, giving a classification of jobs for (1) Beet Sugar, (2) Sugar-houses and (3) Sugar Refineries.)

Potential health hazards of the industry are discussed by Dr. Carey P. McCord with particular attention to sugar as a specific hazard in reference to "sugar dermatitis," the "sugar mite," explosions, and miscellaneous chemical hazards (carbon monoxide, sulphur dioxide, lime, chlorine, carbon dioxide, ammonia and ammonia cyanide, alcohol fumes, inorganic dusts such as charcoal, sulphureted hydrogen and mineral acids), and mechanical hazards.

In a general estimation of the situation, "it is maintained that this industry affords considerable opportunity for occupational impairment of the health of exposed workers." While few specific occupational diseases occur, ill-defined impairments and early degenerative diseases are the ones most inimical to health and such are especially associated with the high temperatures, wetness, and high humidity.—*Industry Report*, Retail Credit Company, Atlanta, Ga., V, 2: 13-24 (Feb.), 1930.

Composition Roofing—This treats of the manufacture of asphalt and asbestos roofing but does not cover such products as wood shingles, tile and metal roofing of various types. There is the usual job classification in which the hazards of each are discussed as well as the commoner occupational diseases which are specified as follows, at least potentially: asbestosis, silicosis, tar poisoning, tar dermatitis, poisoning from "cutting back" solvents, carcinogenetic action of roofing materials, and various other effects of toxic and miscellaneous hazards.—*Indust. Rep.*, 5, 3 (Mar.), 1930. Retail Credit Co., Atlanta, Ga.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Cereals and Rickets. III. The Comparative Rickets-Producing Properties of Corn, Wheat, and Oats, and the Effect of Irradiation and Mineral Supplements—This records an extensive series of experiments on use of activated cereals on rats begun in 1924 and in which a total of 230 rats were employed. Preliminary experiments indicated that untreated cereals were definitely rachitic and at this time a report of an investigation was received stating that cereals do not produce rickets in proportion to their calcium and phosphorus deficiency, and further that oatmeal was the most rachitic and white flour the least, contrary to the evidence found in the preliminary experiments. In these experiments in 1924, young rats were getting an experimental ration of a single cereal for 5 weeks; the rats were then killed and the femurs analyzed. The percentage of ash in the femurs was highest for wheat and lowest for corn meal, rolled oats being intermediate. The experiment definitely indicated that all cereals were ricket producing.

In 1925, experiments were conducted to compare corn, wheat, and oats. The cereals for controls were irradiated in thin layers for 30 minutes by a quartz mercury vapor lamp. In this experiment, the growth on non-irradiated cereals was practically the same, while on the irradiated ration the wheat was superior. Yellow corn was the least favorable. In both these experiments, calcium carbonate at 3 per cent level was included in the feed.

In 1925 and 1926, corn, wheat, and oats, both irradiated and non-irradiated,

were fed with 0, 1, 2, and 3 per cent calcium carbonate addition. In this experiment some rats were fed a ration in which the phosphorus intake was equalized by the addition of H_3PO_4 . In this experiment vitamin A deficiency was manifested. In spite of this, good rate of growth and maintenance prevailed through the 5-week period. Growth on rolled oats was less than on wheat and corn in which the poor consumption of this cereal was a factor. Calcium deficiency of the cereals was evident since when $CaCO_3$ was added up to 1 per cent, growth increased but did not increase with additional calcium. Phosphorus addition made no material change. Wheat was superior in bone production followed by rolled oats and yellow corn in the same relation with the ash in the femurs.

In the experiments in 1926 and 1927, an attempt was made to measure carefully the rations consumed by limiting the intake to that which was all entirely consumed by any one individual. Corn, wheat, and oats were ground to an impalpable powder and fed with wheat gluten and sodium chloride and calcium carbonate. In the rolled oats it was found that these were not consumed readily and the uniform intake could not be insured. The wheat increases were found uniform in untreated cereals without carbonate additions. Irradiation, as in other experiments, made definite growth increases. With calcium carbonate addition there was less increase in weight on the corn diet. In general, the effect of irradiation was to equalize the calcification, but without calcium supplements the percentage of

ash was not increased. Supplementary experiments were run to account for the poor consumption of rolled oats, which seem to preclude the vitamin A deficiency and indigestibility as factors. The opinion is offered that a deficiency of vitamin G may be involved.—H. Steenbock, Archie Black, and B. H. Thomas, *J. Biol. Chem.*, 85: 585 (Jan.), 1930.

The Effect of Vitamin D and of Reaction of Diet upon Response to Parathyroid Extract—Recent investigators have reported the prevention or postponement of tetany by cod liver oil or irradiated ergosterol in parathyroid-ectomized dogs. Others have found that even massive doses of irradiated ergosterol afford little protection. Milk, lactose, calcium lactate, acetate, or carbonate and ammonium chloride, as well as parathyroid extract, have been found to prevent tetany in these cases. In the absence of records as to the effect of parathyroid extract on animals deprived of vitamin D this work was undertaken on young vitamin D-free dogs.

Pups 5 weeks of age were placed on a low phosphorus normal calcium diet. Two in each litter received vitamin D. All grew, but the other animals developed signs of rickets. At the fourth month parathyroid injections were begun when definite rachitic symptoms including lowered serum calcium and phosphates were evident.

One of the dogs receiving the vitamin D complement (1 mg. irradiated ergosterol daily) succumbed to hypervitaminosis D. There was great increase in serum calcium while the corresponding vitamin D-free dog, with neutral urine, showed only slight increase in serum calcium. A dog, vitamin D-free, urine acid, showed less response, but the dog with urine alkaline, vitamin D-free, died of overdosage, indicating the alkaline reaction of the urine as contributing to

susceptibility which was confirmed by supplementary experiments.

Single doses of parathyroid extract had the same effect on young dogs which had been given vitamin D either as cod liver oil or irradiated ergosterol. With a diet producing Ca : P ratio of 1.64 with irradiated ergosterol insufficient to prevent rickets, dogs succumbed to parathyroid extract injections but on a lowered vitamin D-free diet showed no ill effects. The increased response to parathyroid administration with sodium carbonate sufficient to make the urine alkaline was observed both in young and adult dogs. The amount 0.5 gm. per kilo per day of sodium carbonate is sufficient for this purpose. With ammonium chloride substituted for sodium carbonate only slight response is noted. In view of the reports of the use of cod liver oil or ergosterol and calcium salts in the treatment of hyperparathyroidism the authors conclude that these experiments would indicate caution in such treatment.—Agnes Fay Morgan and E. Alta Garrison, *J. Biol. Chem.*, 85: 687 (Feb.), 1930.

Irradiated Products and the Public Health—This is a report of the recommendations adopted by the Conseil Supérieur d'hygiène publique, of which the authors are members. The report is divided into two parts—a discussion of the adverse effects encountered in the use of ultra-violet rays, and the use of irradiated food products. In the latter case, there is quite a complete summary of all of the recent work both in Europe and America on the danger of hypervitaminosis by the administration of irradiated ergosterol.

Reference is made to the warning of the Council of Pharmacy and Chemistry of the American Medical Association relative to the care which should be taken in recommending this new treatment. Reference is also made to the

reports of the toxic symptoms demonstrated by the use of irradiated foods, in particular irradiated milk.

In conclusion, in view of the diversity of the origin and preparation of irradiated products and the changes that take place on aging, it is considered indispensable that the medical profession be exactly informed on the following points: the procedure employed in obtaining the irradiated product, the antirachitic power of the drug, and finally, the date of manufacture. It is important that this information appear on the label and circular and that the date of the manufacture be printed on the case containing the boxes or bottles of irradiated products.

These irradiated preparations should only be distributed by pharmacists.—D. F. Bordas and Jules Renault, *Ann. des Falsifications et des Fraudes*, 253: 37 (Jan.), 1930.

The Escherichia-Aerobacter Group as an Index to Proper Pasteurization—The coli bacillus, because its thermal death-point closely approaches the pasteurization temperature, has been often used as an index to the efficiency of pasteurization. This paper reports experiments to ascertain whether or not there is a relationship between counts of *E. coli* and *E. aerogenes* and the efficiency of pasteurization. One hundred samples of milk were inoculated with pure cultures of *E. coli* and heated for 30 minutes at temperatures used in commercial pasteurization. It was found that *E. coli* survived the heating process in 32 per cent of the samples. As a result of experiments on the acclimatization of *E. coli* to higher temperatures by using resistant individuals selected on successive heatings it was possible to raise from 145° F. to 148° F. the abso-

lute death-point of a culture of *E. coli* the usual or majority death-point of which was 144° F. for 30 minutes.

It is concluded that organisms of the Escherichia-Aerobacter group may survive in milk that has been properly pasteurized and that, therefore, the coli test cannot be used as a true index to proper pasteurization.—E. Arthur Beavens, *J. Dairy Sci.*, 13: 94 (Mar.), 1930.

An Outbreak of Food Poisoning Caused by Salmonella Enteritidis—An outbreak of food poisoning following the ingestion of cream puffs infected with *S. enteritidis* is reported. Ninety people who were made ill displayed typical symptoms of acute gastroenteritis. The average time of appearance of the clinical symptoms was 10 hours after ingestion of the pastry. Delayed symptoms were noted in three of the cases which were mild, illness appearing 24 hours after ingestion. In one case symptoms appeared within 4 hours while in 4 other cases within 6 hours. Subnormal temperatures were noted during the acute stage of the illness followed by slight temperature later in the illness (100–101° F.). All patients recovered.

Salmonella enteritidis was recovered from the cream filling of the pastry; from excreta of mice in the bakery as well as from the intestinal contents of mice trapped in the bakery. Intraperitoneal injections of the recovered organism into mice and guinea pigs cause the death of the animals. Similar injections of killed cultures and culture filtrates both heated and unheated cause death to these animals. Feedings of viable and killed cultures of a number of rabbits and guinea pigs were negative.—Rigney D'Aunoy, *J. Infect. Dis.*, 45: 404 (Nov.), 1929.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The Rural Nurse as a Case Worker—Katherine D. Hardwick, Director of Social Work, Simmons College, has written a splendid article on the pioneering jobs in social work that a rural public health nurse is called upon to do.

As a result of returns from a questionnaire sent to 63 rural nurses in New England, Miss Hardwick summarizes the situation as follows:

The rural nurse as a case worker—Fifty-three of the nurses questioned feel that they bear the brunt of the case work.

Types of problems most frequently indicated with some suggestions for case work procedure—Though the number of cases in rural districts are limited, they usually represent problems most difficult to solve and are most time consuming. The average public health nurse is seldom fully equipped to solve these problems. What shall she do?

1. Leave them alone? Impossible!

2. Form a subcommittee of her nursing committee to take charge of social problems? According to answers received this is not advisable.

3. Meet pressing needs by giving material aid—sometimes out of her own pocket—or organize a relief fund? The experienced nurse knows that relief alone is not the whole story. She must know the cause of the family's difficulty before she prescribes for it.

4. Should she then become a social case worker? Can she? Aside from lack of training, has she the time? Will she not in many instances jeopardize her influence as a public health nurse for the entire community because of the general prejudice against social investigation?

5. And lastly—does the public health nurse really want to do social case work?

Miss Hardwick feels that the public health nurse has been a trail blazer, and

social case workers owe her a debt of gratitude. Why not joint consideration of the problem? Is there no way whereby a competent case worker might help the nurse by sharing experiences and training? Miss Hardwick further suggests that perhaps a joint study committee of the two groups would add to our knowledge of rural problems and strengthen both professions.—Katherine D. Hardwick, *Trail Blazing in Social Work, Pub. Health Nurse*, Mar., 1930, pp. 115-121.

H. L.

To Urban Official Public Health Nursing Agencies—The National Organization for Public Health Nursing committee to study the usefulness, function, constitution and methods of appointment of committees on public health nursing advisory to the public authorities, is most anxious to get in touch with urban official agencies, having such a committee. If you are in an official organization which has a lay advisory committee for its nursing service, will you please notify the chairman of this study committee.—Agnes J. Martin, 419 City Hall, Syracuse, N. Y.

H. L.

The Private Physician and the Public Health—The Bellevue-Yorkville Health Demonstration in New York City has arranged to offer—free of charge at first—the services of a qualified public health nurse a half day a week to each of a selected group of private physicians who wish to put more emphasis in their own practice on preventive work—such as health examinations and supervision, immuniza-

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

tions and the like. Medical laboratory service for private physicians will be given free to patients needing it and at a moderate charge to those who can afford to pay. This experiment was suggested by Dr. Shirley Wynne (New York City Health Commissioner) as a means of furthering coöperation by private practitioners in preventive work for public health.—Preventive Private Practice, *The Midmonthly Survey*, Mar., 1930, p. 712. H. L.

Public Health Nursing in a City Board of Health—From the annual report of the Detroit Department of Health we get a picture of how one large city health department organizes its public health nursing division.

Although nurses are assigned to the different divisions in the department—the School Health Service, Child Welfare, Communicable Disease, Special Investigation, Social Hygiene, Health Education, and several others—the nurses, nevertheless, maintain their identity through the Division of Nursing.

Field nurses are responsible to supervisory nurses in each division; the supervisors, in turn, are guided and directed by the Superintendent of Public Health Nursing who is chief of the Division of Nursing. All rules and regulations pertaining to conduct, efficiency records, employment of new nurses, and question of education, are carried out by the division. A Nurses Council, members of which are elected from each

of the various divisions, has been particularly active in stimulating a desire for providing facilities for education and in developing the general interests of public health nursing.

The city as a whole is cared for on the specialized plan of nursing; there are, however, two districts where a generalized program is being carried on. Nurses entering the Department of Health are given public health training—as very few of them have had any previous public health experience—though no academic credit is given for this training. However, through the coöperation of the College of the City of Detroit, a chair of public health nursing has been established; and the Department of Health, when in need of new nurses, will now be able to procure nurses with some public health training. This course will also give members already in the employ of the Department of Health an opportunity to take extra courses for which they will receive academic credit.

The present population of Detroit is estimated to be 1,429,000. The Department of Health employs 348 nurses—including one superintendent, 33 supervisors, and 314 field nurses. There is a salary range for field nurses from \$2,040.00 to \$1,560.00 a year. The total cost (salaries) for 348 nurses in 1929 amounted to \$666,060.00. The nursing service cost approximately 46.6 cents per capita.—*City Health*—Bulletin Detroit Department of Health, Annual Report, Jan., 1930. H. L.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Health Education in Clinics— Please tell what you do and send samples of printed matter and offer the loan of special devices. For use the morning of Monday, June 9, 1930, in the Health Division, National Conference of Social Work. Address Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Reports of Health Surveys—An examination of several hundred survey reports—inclusive social surveys and specialized studies—shows a wide variety of cover and title page arrangement and of other "front matter." The recently published Health Inventory of New York City, the Welfare Council report, is almost ideal in this respect. The main facts as to its nature, the authors, the local sponsoring organization, the city of publication, and the scope of the study can be gathered quickly at a glance. One weakness is that the date of the study is buried near the bottom of the second page of the preface. As there stated, the data are for 1926, or for 1927 when the other were not available. But some dated 1928 material appears in the text, and a number of the tables, especially those "for one year," are not dated. Otherwise the "front matter" offers what the student and the librarian need for rapid, accurate handling of reports. In contrast many health reports offer needless problems to cataloguers and bibliographers. Particularly when surveys are made by outside agencies it is desirable

that the local distributors of the report should be identified. When, as in the case of Montreal, a special continuing group has been formed, the address of its executive center should be indicated. No local citizen, whose interest has been aroused, should be in doubt as to where to go with questions or offers of service.

What Topic and When?—Have you been reading in this department the collections of topics presented by radio, press releases and monthly bulletins?

Does the diversity of theme suggest questions as to where we are going and how much we are accomplishing? Are there too many topics? Do we present any one topic enough times and in enough different forms to get somewhere in the minds and habits of our constituencies? Is there team-play in any states—between the several state health groups and the different types of local health agencies? Is coöperation in making more of a few topics desirable? Is it practicable? If desirable and practicable what are we doing about it? Whose responsibility is it, anyway?

International Health Exposition—This department of the JOURNAL is delighted that so many public health workers will visit the International Health Exposition at Dresden, and the great permanent Social Museum at Munich.

Graphic presentation of ideas, facts and figures should be bettered amazingly as a result of those visits.

Program committees for national, state, and local groups of health and

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

social welfare groups are urged to give space on programs for a report on graphic presentation as it is done in Germany.

Health Education, Etc.—The following will be discussed in various groups during the National Conference of Social Work (Address: 277 East Long St., Columbus, O.), June 9-14, 1930, in Boston: Clinics as Centers of Health Education, The Interpretation of Social Surveys, Philosophical Basis of Social Work Publicity, How to Develop a Favorable Public Attitude toward the Trained Social Worker, How Evaluate Newspaper Publicity in Social Work? How Make Statistical Data Interesting? What Should the Publicity Worker Know about Social Work? What Constitutes a Reasonable Budget for Publicity? The Factual Basis of Social Work Publicity, Putting Over Probation—The Education of the Public, Publicity Technique Brought Up-to-Date, Putting Life into the Case Work Speech, Relations of the Chest Publicity Director to the Agencies, Raising Money by Mail, National and State-wide Distribution of News, Question and Answer Meeting, Outstanding Publicity Ideas of the Year, Motivation of Public Response to Social Information and Appeals, Division of Responsibility between Community Chests and Member Agencies in Informing the Public, Out of Focus (distorted publicity—with sound), The Year's Publicity Record (Harmon awards).

The education-publicity headquarters will be on the stage of the ballroom in the Statler Hotel.

News Releases—What do you think of this array of topics?

City health departments: Detroit—Early care for tuberculosis, Responsibility for the health of the school child, Scarlet fever prevention; New York—

Dr. Darlington as health commissioner, citizens as unofficial inspectors of neighborhood conditions, public health nursing, business and health, 45th anniversary of Dr. W. H. Guilfooy with city department, weekly report on city's health.

State health departments: Connecticut—Tularemia, New eating place regulations; Illinois—Vitamin D and perfect teeth, Druggists warned against prescribing remedies, Household milk pasteurizing process; Iowa—May Day, Diphtheria; Maryland—Typhoid; North Carolina—Smallpox; Virginia—Open season for flies.

U. S. Public Health Service: Dust-removal systems in granite cutting, Leprosy in the U. S., Prevention of scarlet fever, Malaria in U. S., Control in interstate spread of disease.

American Child Health Association—Clip-sheet on May Day; National Society for Prevention of Blindness—League of Nations' study of motion picture effects on children's eyes.

New Jersey Tuberculosis League: Clip-sheet—Infants protected by health campaign, Tuberculosis takes heavy toll from colored children, Suitable clothing for spring, "Broken homes" through disease, Study of child tuberculosis cases, Lack of rest, Child health spring campaign, Invalid relatives imperil childhood, Nurses in spring health campaigns.

True vs. False Teaching—The use of the schools by manufacturers was discussed by Dr. H. E. Barnard, director of the President's White House Conference on Child Health and Protection, before the Department of Superintendence, National Educational Association. Dr. Barnard said:

Every idea in the field of nutrition has promptly found its way into the schoolroom and carried with it fads and foolishness to command the attention of the teacher and her children until the next new thought supplanted it.

We have used the schoolrooms as a means by which the millions of dollars spent in advertising tooth paste can be translated into profits by committing every school child to the now recognized fallacy that tooth decay is definitely related to tooth paste.

If the tooth brush is used as a symbol for oral cleanliness, just as soap is now made to stand for the sanitation of the outer surfaces of the body, we should by all means continue to urge its use, but when tooth brush drills are premised upon unsound scientific data it is time for the teacher to recognize the difference between fact and propaganda.

Without doubt we have done many things that have been a little help in establishing health knowledge and health behavior. Now it is high time to find out what to do that will be of the greatest help and how to fit it intelligently into our educational system.

Awards for Health Material at Boston—Health agencies should be well represented in the awards to be announced in Boston, June 9-14, by the Social Work Publicity Council, 130 East 22d St., New York, N. Y. *Write for the addresses to which to mail entries in the following classes:* Annual Reports, Letters, Newspaper Articles, Published Photographs, Published Statistics.

Dr. Biggs Believed in Health Education—Among public health objectives as outlined by Dr. Herman M. Biggs in his last address, May 17, 1923:

Provision of systematic instruction in elementary physiology and hygiene and in health habits in the primary and secondary schools, and more extensive instruction in the normal schools and universities.

Postponement of the age at which death occurs from the cardiovascular diseases and the other diseases of later life, through physical examination and instructions as to methods for retarding or arresting their progress.

The prevention by education and law enforcement of new infections in the venereal diseases, and provision for more adequate treatment of syphilis.

The extension of the educational work of the public health authorities as a most effective means to promote the preservation of health and the prevention of disease.

HONORABLE MENTION

To Racine (Wis.) Board of Health: for its successful mimeographed annual report for 1929.

To the State Charities Aid Association of New York: for its 1928-1929 annual report—for its title, "A Year of Citizen Service in Health and Welfare"; the table of contents, illustrations, and general make-up.

To Welfare Council of New York City: for the cover, title-page and other "front matter" of A Health Inventory of New York City—for completeness and clarity of arrangement.

To Illinois Department of Public Health: for annual report with an index (but lacking table of contents); for numerous diagrams and statistical maps.

REPORTING

A Public Health Program on a Fact Basis. Cleveland (O.) Health Council, 715 Superior Ave., N.E. A 4-page folder listing "Fact Finding Studies," with the corresponding list of "Action Based on Results." *Free.*

A page statistical report in the 1929 annual report of the Infant Welfare Society, Chicago, Ill., is divided under "Infant," "Pre-School," and "Pre-natal." *2 cents a copy.*

The annual report of a county nursing service in New York contains no office address, no address for securing service.

Milestones in Health and Welfare, a summary of 57 years of work by the State Charities Aid Association, 105 East 22d St., New York, N. Y. 28 pp. *Free.* Should be suggestive to a local, state or national agency in recording past activities.

Telling the Story in Graphic Form, by Charlotte Heilman. *Red Cross Courier*, Washington, D. C., March 15, 1930. Describes and illustrates 8 kinds of data a visiting nurse association may

express through diagrams—for annual report or office use. *Free.*

Its Major Activities. Connecticut State Dept. of Health, Hartford, 1929. 12 pp. Every bureau and division is presented in concise paragraphs as follows:

Bureau of Public Health Instruction—

Keeps the department activities to the forefront in all parts of the state and spreads health information through the following activities:

Supervision and preparation of weekly and monthly health bulletins

Placing and distributing health educational material such as moving picture films and equipment, health posters and health leaflets

Making arrangements for lectures and public health courses

Planning and installing health exhibits

Reviewing new illustrative material and new methods of presentation and recommending the purchase of new equipment or the adoption of new methods to further health educational work

Keeping in close touch with health leaders and local organizations to encourage a wider use of the department health educational service

Studying local health trends so that the health educational service may adequately meet the needs of local organizations and community groups

Assisting local groups in planning health meetings

Under the supervision of this bureau is carried on through:

Nutrition articles, leaflets, and a nutrition handbook

Lectures and nutrition courses for public health nurses and other leaders

Nutrition exhibits

Advice on nutrition problems in the field

CONTESTS

Listening in on the National Press Club spelling bee prompts me to offer again the suggestion that a health spelling bee contains possibilities!

The ninth annual health poster contest has been conducted by the Anti-Tuberculosis Society of Schuylkill County, Pa. Subject: Nutritious foods.

National Safety Council, Chicago, Ill., is conducting the second Inter-City

Motor Vehicle Fatality Contest. Ends August 31, 1930.

A state-wide junior high school essay contest on "Protecting Health in Youth" was a feature of the Early Diagnosis Campaign in Michigan.

The American Eugenics Society, New Haven, Conn., is conducting a competition open to clergymen of all faiths for prizes aggregating \$1,000 for sermons on "Religion and Eugenics: Does the Church have any responsibility for improving the human stock?" Closes July 30.

"Minnesota high school girls presented many different interpretations of the pamphlet "It and How," published by the Minnesota Public Health Association, as a part of its teen age campaign, in a state-wide contest just completed." Two prize essays appear in *Everybody's Health*, St Paul. March, 1930. 10 cents.

The Journal of the Outdoor Life, 370 7th Ave., New York, N. Y., will pay for photographs suitable for publication. To be rated for (1) subject matter, (2) composition, (3) technical excellence. \$1.00 to \$5.00 for each photograph accepted. *Why not conduct a local competition, sending the winners to the Journal?*

Subjects for Photographs—Human interest scenes showing some phase of cure-chasing. Suggestions include outdoor or indoor scenes for all seasons of the year (not buildings), children, groups of patients doing something such as occupational therapy, taking heliotherapy, walking, listening to the radio, nature study subjects of birds and flowers, or any other scenes typical of life in and about a sanatorium or elsewhere in the life of a cure-chaser. Posed groups looking at the camera have no photographic interest nor value. All photographs in which real people appear must be accompanied by written permission from each of these persons saying that he or she is willing to have the picture published, and also a statement of where the photograph was taken.

Iowa High School Public Speaking Contests. Extension Dept., University

of Iowa, Iowa City, Ia. Describes Iowa High School Debating League. When will we have a health debate contest? 10 cents.

RADIO

Four Heart Talks, by president of Heart Council, 312 West 9th Street, Cincinnati, O. Listeners were asked to enclose 6 cents in postage. "Nearly 500 requests from 33 states, and requests are still coming."

The "Careful Twins," "Handy Andy" and "Ready Eddy," conduct the Careful Children's Club of the St. Louis Safety Council in a nightly 10-minute period over Station KMOX. Running steadily for 3 years. Club has nearly 500,000 members in 45 states and 6 foreign countries.

A Red Cross Play for the Radio. *Red Cross Courier*, Washington, D. C., March 15, 1930. *Free*. Full script of "One Working Day in Red Cross Service," a 15-minute radio play given by Lancaster (Pa.) Chapter. The announcer carries some of the heavy work in presenting bald facts.

More than 200 stations are using the twice-a-month broadcasts prepared by the U. S. Public Health Service, Washington. *Copies free*.

Every Wednesday, 5 p.m., via Station USYR (Syracuse, N. Y.) the Onondaga Health Association will broadcast the "Live a Little Longer Club."

Every Wednesday, 7:40 p.m., via WGY (Schenectady) New York State Department of Health continues its broadcasting which has been running regularly for several years.

Recent broadcasts include items listed below.

Connecticut State Department of Health: The Health Traffic Officer (the health officer).

New York City Health Department: Sleep and Rest, Help! Police!! I've Been Robbed!!! (health examinations), First Aid, Measles.

New York State Department of Health: The Weather and You, The Milk Problem Boiled Down.

U. S. Public Health Service: The Public Health Nurse.

EDUCATIONAL MATERIAL

Rural Health, by R. A. Felton and N. V. Short. New York State College of Agriculture, Ithaca, N. Y. 38 pp. What can be done; the county health department. Copy largely adaptable to other states. 10 cents.

National Tuberculosis Association, 370 7th Ave., New York, N. Y. Revised 16-page booklet listing "pamphlets and circulars, books, motion pictures, posters and periodicals" issued by the N. T. A. *Free*.

We list in this section from time to time educational material from commercial sources, usually those free from promotion of individual brands. Some day we hope for the evaluation of such publications and the thorough discussion of the use of material supplied by manufacturers, and the formulation of policies for their use by health workers.

Some Foods for Children (6 months to 6 years). Evaporated Milk Assn., 231 S. La Salle St., Chicago, Ill. *Free*.

The Cause and Prevention of Tooth Decay. 8 pp. Kolynos Company, New Haven, Conn. *Free*.

Household Refrigeration Bureau, National Association of Ice Manufacturers, 51 Chambers St., New York, N. Y. Series of pamphlets on the care of foods passed upon by a committee including representatives of Bureau of Home Economics of U. S. Department of Agriculture, American Hospital Association, American Home Economics Association, etc. *Free*.

BOOKS AND REPORTS

Recent Advances in Preventive Medicine—By J. F. C. Haslam, M.C., M.D. (Edin.), M.R.C.P., D.P.H. With a Chapter on the Vitamins by S. J. Cowell. Philadelphia: Blakiston, 1930. 328 pp. Price, \$3.50.

This book is one of the "Recent Advances" series. The author has taken Sir George Newman's *Outline of the Practice of Preventive Medicine* as a framework around which to build his account of the progress in this line of medicine.

Opening with a chapter on eugenics, practically all the problems which are now engaging medical attention are given due consideration. In addition to eugenics, which necessarily brings in much concerning children, some 50 pages are given to childhood, an equal number to milk, and approximately 40 pages to diphtheria and scarlet fever; so it is evident that infancy and childhood get a large share of attention. The special chapter by S. J. Cowell on vitamins is excellent.

We wish particularly to commend the author's condemnation of vaccines against the common cold. The entire book deserves high praise, and only minor points are deserving of criticism. Calmette's vaccine is dubbed "B. C. G.," which is not the name the inventor gave to it. On page 112, he quotes Mummery's last paper as 1926, he having died that year, and on the next page he suggests that the views expressed may possibly not be the latest held by that writer. How shall we find out?

The book is admirably printed and can be recommended without reserve.

M. P. RAVENEL

Psychology and Industrial Efficiency—By Harold Ernest Burtt, Ph.D. New York: Appleton, 1929. 459 pp. Price, \$3.00.

On the premises that the employee has been hired by the proper scientific procedure, there is to be considered the important question of the most effective method of organizing his work from that point on. Thus the present volume deals with applied psychology in the matter of promoting industrial efficiency, the text being in everyday vocabulary.

The material is divided into 10 chapters, logically arranged with subheadings, various tables, graphs, footnotes, page references, and chapter summaries, with an adequate table of contents, but a rather brief index.

After the scope of the problem and its limitations there follows a fine discussion of applying educational principles to learning in industry, and a comprehensive review of economic methods of work for the individual and the group.

Fatigue is considered both from its psychical and its environmental relations—the latter rather too briefly, with no consideration of physiological origins and differences in such matters as nutrition, elimination, circulation, and bad personal hygiene, or the recognition of the importance of disease states and especially "silent sickness," as chronic degenerative afflictions are aptly called by Fisk. As some of these personal states are almost constantly bobbing up, and at least indirectly influencing the mental state, one feels they can hardly be overlooked for any group of workers, no matter how scientifically they may have been selected upon employment. Due attention is given to the reports of

the British Industrial Fatigue Research Board but the author overlooks Bedford's "Ideal Work Curve" as one of the possible methods of gauging fatigue in industry.

There is an excellent discussion on "Satisfaction and Morale" and a psychologist's view of the subject of accidents. A chapter on "Efficiency in Executive Work" rightly warns of "gold brick" psychology, "mental dynamisms" and similar quackery, and in an entertaining manner presents the subjects of attention, memory, and habit formation. It is claimed that industrial psychology is playing a larger rôle in Europe than in America, but we doubt if with as great success in view of the preponderance of industrial disputes abroad as contrasted with the present-day "get-together" policy of employer and employee in this country.

Coöperation of other experts with the psychologist, notably engineers, is cited. Truly the efficient management of the "human machine" requires the services of several types of experts, and at present there is not enough coöperation between them, each feeling that his own field about covers the subject.

This book is by an able and experienced psychologist already favorably known for his work on *Principles of Employment Psychology*. It considers a most important side of personnel management, with the aim of suggesting better methods of work and better results with the same effort.

EMERY R. HAYHURST

Milk and Milk Products—By C. H. Eckles, D.Sc., W. B. Combs, and Harold Macy, Ph.D. New York: McGraw-Hill, 1929. 379 pp. Price, \$3.50.

The latest of several recent contributions to the literature on dairy science is a more or less elementary textbook for agricultural students. It covers the

field in a thorough and comprehensive manner, discussing the composition and properties of milk, the various micro-organisms which influence it, the common dairy processes, the manufacture and use of dairy products, and their place as food. A chapter on market milk has a sound, but rather sketchy outline of sanitary methods. One striking characteristic of the book is that it has no bibliography and practically no references. The book is well printed, competently illustrated, and has a good index. It should prove of value to those who have to deal in an official or commercial capacity with milk and its many important products.

JAMES A. TOBEY

The Art of Rapid Reading—By Walter B. Pitkin. New York: McGraw-Hill, 1929. 233 pp. Price, \$2.50.

Mr. Pitkin offers a life-preserver to the man who is slowly sinking in the accumulation of books and periodicals that he knows he should read for his own best interests, but for which he cannot find time in his busy life. The public health worker should at least examine the proffered assistance.

The author argues that writing is improving and the output of printed matter is larger and increasingly better, but that our reading has not speeded up and improved in proportion. In the first part of his book, Mr. Pitkin diagnoses various reading troubles. In the second and third parts he suggests ways to improve "word habits" and "eye grasp." The fourth section is devoted to the art of "skimming," and suggests a technic for grasping salient points. The fifth section deals with practice exercises. He includes a progress chart upon which to record one's improvement, and a brief but adequate index.

The book is for study and would probably profit the conscientious stu-

dent. The eye tests are interesting and those made by this reviewer show an astonishing variation among individuals in the number of words taken in at a glance. The least valuable feature of the book is that it makes excellent dinner-table conversation.

Mr. Pitkin's examples of light, average, solid and heavy reading are not always apt. They would be more valuable if they were of more general interest. It is to be remembered, however, that the book is written for the busy business man who wishes to increase his capacity for informing himself. It does not relate to reading for pleasure or what Mr. Pitkin calls "revery reading." One puts aside the book with the reflection that we have had "The Art of Thinking," "The Art of Reading," and now we have "The Art of Rapid Reading." Will someone come to the rescue with "The Art of Remembering"?

W. M. RAYNE

Bergey's Manual of Determinative Bacteriology: A Key for the Identification of Organisms of the Class Schizomycetes—By David H. Bergey. (3d ed.) Baltimore: Williams & Wilkins, 1930. Price, \$6.00.

The general plan of the Manual is the same, except that it has been enlarged by the addition of new tribes and genera, and over 200 new organisms most of which fall into the genera of flavo-bacterium, pseudomonas, phyto-monas, lactobacillus, and bacillus, so that the keys for these genera have been re-fitted. The former dysentery group has been separated from typhoid under the euphonious name of "Shigella." Why our old friend *B. lactis aerogenes* should be separated from its associates *B. pneumoniae* and *B. rhinoscleromatis*, et al., and made the head of a separate genus is still beyond me. The only apparent distinction being that one occurs usually in the digestive tract and the other in the respiratory. The re-

cent attack of psittacosis might lead us to believe that such separations are doubtful, and depend mainly on the animal involved.

On the whole, however, there seems to be a greater degree of conformity to the original recommendations of the S. A. B. It still seems unfortunate that this book is accepted abroad as the final word on American opinion. Perhaps each succeeding edition may show improvement.

ROGER G. PERKINS

The Visiting Teacher at Work—By Jane F. Culbert. New York: Commonwealth Fund Division of Publications, 1929. 235 pp. Price, \$1.50.

"The aim of this book is to present in sensible and practical form a discussion of the professional standards, procedure, and administrative relationships of the visiting teacher." The lapse of more than twenty years since visiting teacher service was introduced into the public schools has made possible an authoritative study and treatment of these phases of health and education.

The book is divided into two parts: Work with the Child, and Professional Standards and Relationships. There is a group of appendixes covering types of records and forms, and also a bibliography.

The visiting teacher must ask of the school, "How can the school process best fit the needs of this child?"—of the home, "What in the family or home environment is preventing this child from realizing his potential power, and experiencing his best service in his civic relations?"—of the community, "What lack or obstacles for which the community is responsible are preventing this child from receiving his just share of opportunity for physical, mental, and spiritual growth?"

The problems with which she must most frequently deal are those of "poor

or failing scholarship, behavior, unfavorable physical and environment conditions, unsatisfactory relations with companions or with those in authority, hampering, unwholesome and personal traits."

The table of types of problems indicates that poor scholarship stands at the top of the list, being 37 per cent more common than any other cause. As poor scholarship frequently results from poor physical condition, or absence due to illness, it would seem that health problems enter more largely into the situation than the tabulation (410 cases of special health problems out of a total of 11,588 cases) would indicate. This seems proved by a later table, showing the "factors in the children themselves considered by the visiting teacher in making a diagnosis and plan of treatment," which places physical disabilities at the top of the list.

As to the attitudes and conditions existing in the school as potent factors in affecting adjustment, that of an unsympathetic teacher is the one most commonly found. The most effective measure in assisting the school to adjust the children was found to be "bringing about better understanding of home conditions."

To be successful, the visiting teacher should know first the child and its family; second, the community; third, the schools. She must demonstrate that she is neither a "fad" nor a "fancy." She must establish friendly and co-operative relations with school principals, teachers, nurses, and with other specialists who come in contact with pupils. The most important relation, outside of that with the child itself, is that with the classroom teacher.

Miss Culbert, being Secretary of the National Committee of Visiting Teachers, and thoroughly familiar with their activities throughout the country, is in a peculiarly advantageous position to

compile a book of this sort. Its content should be part of the information of all teachers, principals, and other school administrators, of school physicians and school nurses, of social workers, mental hygienists, and other specialists in child problems.

Somewhat closer punctuation would make the text easier reading.

CHARLES H. KEENE

Our Baby's First Seven Years—By Hermien D. Nusbaum. Chicago: Reilly and Lee, 1928. 85 pp. Price, Keratol Cloth, \$2.50, Silk Moire, \$4.00.

This book is planned for a combined physical and sentimental record of a child's first seven years. It is a very attractive and complete "Baby Book" the filling of which will be a joy to intelligent parents and a real value to the child.

A foreword by Dr. J. B. DeLee stresses the importance of a careful, full "record of physical changes, of growth, of sickness, and other conditions to which the physician could refer for discovery of constitutional tendencies or of acquired susceptibilities." Ample space is provided for records of this nature, a partial list of which follows:

- Doctor's observations of facts of birth
- Accurate measurements
- Identification marks, including foot and finger prints
- Records of weight, height and growth
- Complete form for medical examination
- Feeding records
- Muscular and mental development
- Teeth tables
- Personal habits
- Illness and injuries
- Preventive measures against diseases

A blank form for a three-generation pedigree is provided. A page for "Outstanding talents and characteristics of antecedents" will probably remain blank in peace-loving families.

A carefully selected list of pamphlets, magazines, and books dealing with the physical and mental health of children

and parental responsibilities is given which should be of real assistance to the conscientious father and mother.

The only suggestion that might be made for the completion of the health pages of the book is the inclusion of scarlet fever and measles in the list of diseases against which preventive measures are taken.

The binding, illustrations in colors, and the general make-up of the book are very attractive indeed and no nicer present could be given to the household that is boasting a new baby.

JOHN HALL

Burdett's Hospitals and Charities, 1930. *Being the Year Book of Philanthropy and the Hospital Annual—Founded by Sir Henry Burdett, K.C.B., K.C.V.O.* London: Nursing Mirror, Ltd., 24 Russell Square, W.C. 1, 1930.

The 1930 edition of this valuable guide for the 40th year of its existence is at hand. The entire volume concerns Great Britain and Ireland. The chapter "The Voluntary Hospitals" gives a review which is of interest to all concerned in such institutions. Among the features are the facts that more than half the hospitals which made returns showed deficits amounting in all to considerably more than 5 million dollars; that the number of available beds increased by 3,095, 81 per cent of which were occupied daily; that motor accident cases have cost voluntary hospitals approximately a million dollars during the year, and are on the increase, becoming constantly a greater burden, so that compulsory insurance has been suggested. The cost of radium has become a matter of concern to all hospitals.

During the year an International Hospital Conference was held in Atlantic City, N. J., at the invitation of the American Hospital Association, at which new ground was broken.

With the exception of these features, the book is made up of a systematic directory of institutions and philanthropic bodies, medical schools and colleges, nursing and convalescent institutions, institutions for the blind, sanatoriums, etc. An admirable index makes its material available. As a book of reference, it is extremely valuable, and the information it contains may come in handily for the many thousands of Americans who will visit England and Ireland during the year and are liable to fall ill while abroad.

M. P. RAVENEL

The Rat. A World Menace—By A. Moore Hogarth, F.E.S. With Preface by Sir Thomas Horder, Bart. London: John Bale, Sons and Danielsson, Ltd., 1929. 112 pp. Price, \$2.50.

This little book is timely, as we have recently been told that the rat population of the United States is more than 125 million, and that each person in this country pays \$2.00 per annum for the upkeep of one rat.

The rat is an economic scourge; from the public health standpoint, it is a menace. The preface by Sir Thomas Horder expresses surprise that so little has been done toward the extermination of carriers of disease. In England, there is now the College of Pestology, the object of which is to teach the danger of carriers and the methods of dealing with them.

The present volume gives the history, geographic distribution, species, habits, etc., of rats; tells of their fecundity; the amount of food consumed and danger caused; describes methods of getting rid of them, and preventing their increase.

The book is small and light, and can be heartily commended for general as well as professional reading. Certainly increased activity in the destruction of rats is needed throughout the world.

M. P. RAVENEL

A System of Bacteriology in Relation to Medicine, Vol. IV—By H. J. Bensted, W. Bulloch, L. Dudgeon, A. D. Gardner, E. D. W. Greig, D. Harvey, W. F. Harvey, T. J. Mackie, R. A. O'Brien, H. M. Perry, H. Schutze, P. Bruce White, and W. J. Wilson. London: His Majesty's Stationery Office, 1929. 482 pp. Price, \$6.00.

The second volume of *A System of Bacteriology in Relation to Medicine*, published by the Medical Research Council, is No. IV, devoted largely to the organisms usually described as the colon-typhoid group. Needless to say, these are among the most interesting and important organisms met with. This alone would make the volume of outstanding importance. They are divided into *Bacillus Typhosus*, 66 pages; Salmonella Group, 65; Dysentery Group, 94; Colon Group and Similar Bacteria, 81. Approximately 110 pages are given to The Cholera Vibrio and Related Organisms, and 27 to the Pasteurella, to which the name of Trevisan, who proposed the name in honor of Pasteur, is attached. A final short chapter is given to *Pseudotuberculosis Rodentium*.

The general plan is to consider each group as a whole, after which the individual organisms are taken up in detail. The histories written by W. Bulloch are deserving of especial mention. It is safe to say that nowhere can one find the essential facts more clearly and concisely put. Under typhoid fever, he calls attention to a fact very little known—that Bretonneau, the author of the classic description of diphtheria, was the first to maintain that typhoid fever was contagious, that it was accompanied by a specific intestinal "eruption," and that one attack conferred protection. This was written in 1829, and resurrected in 1922 by Dubreuil-Chambardel.

Some of the classifications are rather surprising. The fluorescens-pyocyanus group is included in the chapter on the colon, and we are even given some points

of differentiation between the pyocyanus and the colon.

The book as a whole calls forth nothing but praise. Every subject is discussed as fully as is necessary, and the reader is left with a clear conception of the matter under discussion. In every respect it is up-to-date. Each chapter ends with a well selected bibliography. There is a welcome absence of the endless discussions too often found, which end nowhere.

Everyone who has seen the two volumes so far issued will look forward with eagerness to the rest of the series. The printing is excellent, the paper light with mat surface. If the other volumes keep up to the high standard of those issued, as we have no doubt they will, it can be stated with assurance that there will be no publication in the world containing a more authoritative exposition of our knowledge of the science of bacteriology.

M. P. RAVENEL

The Village Doctor—By Sheila Kaye-Smith. New York: Dutton, 1929. 266 pp. Price, \$2.50.

This charmingly written story conveys a convincing health lesson. A well educated, up-to-date physician whose health requires him to leave London acquires a practice in an old rural district. His ideas about pure drinking water are combated with the old, old argument about fathers and grandfathers having used the supply without harm. Finally a severe epidemic of typhoid fever predicted by the new doctor convinces the authorities that they are wrong in using the same stream both as a sewer and as a source of water. However, his chief convert, who is also a political power in the community, is made by the doctor's kindly advice concerning a highly valued sick cow!

The book has had 17 printings in 2 months, which proves that it is charmingly written, and has the human interest quality.

M. P. RAVENEL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Meningitis Control—The Massachusetts State Health Department offers a meningitis diagnostic service to the physicians of the state similar to the services it performs for cases of poliomyelitis. Local boards are urged to isolate cases for 2 weeks and until symptoms clear up; contacts are isolated for 10 days.

ANDERSON, G. W., and BIGELOW, G. H. Epidemic Meningitis Control. *New Eng. J. Med.*, 202, 11: 518 (Mar. 13), 1930.

Standard Methods of Water Analysis—This is a report of the Committee of Standard Methods for the year 1928–1929. Much valuable research is reported upon and 25 recommendations are recorded.

ANON. Report of Committee No. 1 on Standard Methods of Water Analysis. *J. Am. Water Works A.*, 22, 2: 242 (Feb.), 1930.

Self-Disinfection by the Skin—The power of the skin to destroy bacteria was tested. The results of the tests are not entirely clear to this superficial reviewer.

ARNOLD, L., *et al.* The Self-Disinfecting Power of the Skin. *Am. J. Hyg.*, 9, 2: 345 (Mar.), 1930.

Responsibility for Cancer Control—The responsibility of the health official, the research worker, the dentist, practicing physician, nurse and social worker, the educator, journalist, etc., in the world-wide cancer control project is allotted to each group.

BLOODGOOD, J. C. Cancer as a World Problem. *New York State J. Med.*, 30, 5: 255 (Mar. 1), 1930.

Milk Sanitation Essentials—The diseases to be guarded against are diar-

rhea, tuberculosis, other communicable diseases (including undulant fever). The answer is, of course, pasteurization; the job, stimulating public demand for pasteurized milk.

BROOKS, P. B. Essentials vs. Non-Essentials in Milk Sanitation. *New Eng. J. Med.*, 202, 12: 582 (Mar. 20), 1930.

British Maternity Service—This discussion of the objectives and methods to be employed in providing a national maternity service will be read with interest by American health workers.

CASSIE, E. A National Maternity Service. *J. Roy. San. Inst.*, 50, 9: 581 (Mar.), 1930.

Influenza Epidemics—This is a detailed study of the origin and progress of 6 epidemics of influenza which occurred from 1920 to 1929. A quarter of a million deaths were recorded, one-half as many as in the pandemic of 1918–1919. An important contribution.

COLLINS, S. D. Influenza-Pneumonia Mortality in a Group of about 95 Cities in the United States, 1920–1929. *Pub. Health Rep.*, 45, 8: 361 (Feb. 21), 1930.

Nuclear Response in Yellow Fever—Reporting studies leading to the conclusion that the nuclear response in yellow fever is of the same general type which occurs in chicken pox, herpes, and other virus diseases.

COWDRY, E. V., and KITCHEN, S. F. Intracellular Inclusions in Yellow Fever. *Am. J. Hyg.*, 11, 2: (Mar.), 1930.

Colds—An inclusive review of laboratory and field research in regard to the cause and prevention of colds leading to these conclusions: colds are "seasonable"; no microorganism has been demonstrated; no prophylactic

method is of unquestioned value. Suggestions for further research are appended.

DOULL, J. A. Acute Endemic Upper Respiratory Disease. *Canad. Pub. Health J.*, 21, 3: 105 (Mar.), 1930.

Visiting Nurse and Hospital Service—An interesting story, well told, of the development and organization of a county nursing service, from and by the Englewood (N. J.) hospital. The combination of administration works to the mutual benefit of each.

EDGEComb, M. E. Public Health Nursing under the Englewood Plan. *Pub. Health Nurse*, 22, 3: 126 (Mar.), 1930.

New Haven Tuberculosis Program—The organization for the control of tuberculosis in New Haven has unique features. The generalized nursing plan and the advantages of the polyclinic are discussed.

EDWARDS, H. R. The Tuberculosis Program in New Haven. *Am. Rev. Tuberc.*, 21, 2: 233 (Feb.), 1930.

Tuberculosis Research—Telling about the fundamental chemical studies upon the tubercle bacillus and the physiological effects of the chemical fractions. The promising work will be continued in a number of widely separated laboratories.

EMERSON, K. Research in Tuberculosis. *J. A. M. A.*, 94, 11: 759 (Mar. 15), 1930.

Venereal Diseases in Toronto—A survey is reported of venereal disease cases under medical care in the city of Toronto. The rate 8.4 per 1,000 is lower than the corresponding rates reported from 14 cities in the United States.

FENWICK, C. P. Venereal Disease Survey of Toronto. *Canad. Pub. Health J.*, 21, 3: 132 (Mar.), 1930.

Yellow Fever Virus—This reports the inability to demonstrate the pres-

ence of any particular organisms in the blood of monkeys infected with yellow fever. Other important findings are recorded.

FROBISHER, M. Properties of Yellow Fever Virus. *Am. J. Hyg.*, 11, 2: 300 (Mar.), 1930.

Cancer Bacteria?—Reporting the elaborate life cycle of an exceedingly pleomorphic microorganism which the author succeeds in recovering from various types of malignant lesions.

GLOVER, T. J. The Bacteriology of Cancer. *Canada Lancet*, 74, 3: 92 (Mar.), 1930.

Underpar School Children—Twenty-eight tuberculosis suspects were given cod liver oil; they gained an average of 6.7 lb. compared to 3.25 lb., the average of normal school children of the same age. At the same time there was experienced a decrease in abnormal temperatures and an improvement in school attendance and scholarship.

HOLMES, A. D., and ACKERMAN, H. L. The Value of Cod Liver Oil for Underpar Children of School Age. *New Eng. J. Med.*, 202, 10: 470 (Mar. 6), 1930.

European Milk Borne Epidemics—Epidemiologic studies of milk borne communicable disease outbreaks are reported. They make a valuable addition to America's "exhibit A." Professor Madsen's answer is the same as ours: efficient pasteurization.

MADSEN, T. J. M. Milk Epidemics. *Pub. Health*, 43, 6: 168 (Mar.), 1930.

Water Supply Contamination—Ingenious devices thought out by consumers for the contamination of water systems form an interesting commentary on human frailties.

MORRIS, S. B. Contamination of Water Systems by Consumers' Water Uses. *J. Am. Water Works A.*, 22, 2: 180 (Mar.), 1930.

British Experience with Alcoholism—The causes of the "remarkable decline in mortality of diseases associated with excessive consumption of al-

cohol" are: changes in personal hygienic habits; enormous extension of counter-attractions to the public house; curtailment of hours of sale. Educational campaigns for temperance are suggested for the use of local authorities. Whether the British method is inferior to our constitutional short-cut is a field for absorbing, but largely profitless, speculation.

NEWMAN, G. Alcohol and the Public Health. *Med. Off.*, 43, 8: 83 (Feb. 22), 1930.

Scarlet Fever Prophylaxis—Contacts given human immune serum developed scarlet fever to the extent of 2.9 per cent; 12.8 per cent of the unprotected contacts developed the disease. Immunity lasts not longer than 3 or 4 weeks. Prophylactic treatment is recommended for very young and infirm contacts.

MEADER, F. M. Scarlet Fever Prophylaxis. *J. A. M. A.*, 94, 9: 622 (Mar. 1), 1930.

Heredity vs. Environment—Sir Thomas's presidential address at the Institute of Hygiene (British) explores again this ancient and familiar controversy, concluding hopefully, "In some unknown manner a close association is established between structure and function so that while heredity perpetuates, fresh powers from environmental sources are added whereby heredity becomes enriched with the passing of the generations and the further evolution of the race is secured."

OLIVER, T. Heredity, Environment, Opportunity. *Med. Off.*, 43, 9: 97 (Mar.), 1930.

Etiology of Poliomyelitis—Further reports on the study of the pleomorphic diplococcus of poliomyelitis and the results of treatment of cases with antiserum. This controversy bids fair to equal that raging about BCG.

ROSENOW, E. C. Poliomyelitis Antistreptococcus Serum. *J. A. M. A.*, 94, 11: 777 (Mar. 15), 1930.

Vitamins in Malted Milk—Malted milk was found to be rich in vitamins A, B (B_1) and G (B_2) when assayed biologically.

QUINN, E. J., and BRABEC, L. B. The Vitamin A, B, and G Content of Malted Milk. *J. Home Econ.*, 22, 2: 123 (Feb.), 1930.

Tuberculosis Decline—Is tuberculosis, improved physical status, or better public health facilities the cause of the decline in tuberculosis case and death rates? It would not be fair to the author to give away his answer here. The paper is easily available; read it and the ensuing discussion.

SHEPARD, W. P. A Review of Factors Involved in the Decline of Tuberculosis. *J. A. M. A.*, 94, 10: 697 (Mar. 8), 1930.

Child Guidance—Looking back over the years of experience in child guidance, the author concludes that the clinics have helped parents, social workers, nurses, pediatricians, psychiatrists, and persons dealing with juvenile delinquency, as well as the children actually studied.

SMITH, S. K. Child Guidance Clinics. *J. A. M. A.*, 94, 10: 710 (Mar. 8), 1930.

Dysentery Outbreak in Prison—An outbreak of dysentery (Flexner type) in a prison provided an unusual opportunity for the study of the disease. The results of administering bacteriophage were inconclusive.

STANLEY, L. L. Prison Epidemic of Flexner's Dysentery. *J. A. M. A.*, 94, 12: 857 (Mar. 22), 1930.

Weighing and Measuring—Shall we weigh and measure school children, in view of the American Child Health Association's findings? Weigh?—Yes, with certain limited objectives. Use height-weight tables to determine nutritional status?—No.

WHITNEY, A. The Weighing and Measuring of School Children. *Child Health Bull.*, 6, 2: 39 (Mar.), 1930.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Connecticut—Connecticut's "Banner Health Year" was 1927. As shown by the 43d report of the 51st year of the State Department of Health for the year ending June 30, 1928, the 1927 general death rate of 10.6 per 1,000 is a record low, as was the infant mortality rate of 58.4 per 1,000 births and the specific death rates for typhoid fever (1.1 per 100,000), scarlet fever (1.4), whooping cough (2.5), tuberculosis, all forms (66.8), pulmonary tuberculosis (57.6), and diarrhea under 2 (11.5). The prevalence of communicable diseases in the state was at a minimum. The total of 24,428 cases of reportable diseases was the smallest since 1917.

The task of surveying the state for hospitals required to be licensed by the department, by the law passed in 1927, was carried out by the Bureau of Preventable Diseases. There were 45 hospitals licensed for the year, of which number 29 were for chronic and convalescent cases only. This bureau also introduced the plan of sending out forecasts of threatened epidemics of diphtheria, smallpox, and poliomyelitis to the health officers and physicians of the state.

The allocation of births and deaths was begun by the Bureau of Vital Statistics, to be effective for the year 1927 and thereafter. A form notice is sent to the registrar to whose jurisdiction the death is being charged, no actual transference of records taking place, though copies of birth and death records of non-residents are sent to the registrars of the cities where the parties concerned are residents. The allocation of births is done according to the residence of the mother.

The major activities of covering 110 water supplies furnishing water to 136 communities, carrying on the super-

vision of 16 filter plants and 44 chlorination plants, the covering of 33 sewerage systems having some form of *treatment before final disposal*, the checking and supervision of swimming pool operations, and the shellfish program, constitute the major activities of the Bureau of Sanitary Engineering. In addition, the inspection and control of a rapidly increasing number of wayside eating places and summer boarding camps is a state necessity covered by this bureau.

The routine work in child hygiene has increased; from 50 to 55 well child conferences were operated with the assistance of local physicians and officials during the year. A total of 7,819 children attended, in which 726 physical defects were found. The Summer Round-up of children about to enter school for the first time, which was started two years before, was held in 1927 in 32 towns and covered over 1,000 children. The May Day Program initiated by the American Child Health Association has been designated by the governor as Child Health Day.

The volume covers 411 pages, containing tables and charts illustrating every phase of state health activity. Numerous photographs are interspersed throughout the text, which is improved for use by an excellent table of contents and an index.

Palo Alto, Calif.—This annual report for the calendar year 1929 came off the press February 21—an excellent record! The report opens with a clear organization chart of the health department, followed by 7 photographs skillfully arranged on a single page to acquaint the reader at a glance with the scope of activities.

On the basis of 13,200 population, a

resident death rate of 9.9 per 1,000 is recorded. There were 10 infant deaths, giving an infant mortality rate of 62.1, but for the 10-year period 1920-1929, an infant mortality rate of 41.3 is noted. During the year bonds were voted for a new hospital to cost \$450,000 which will provide isolation and laboratory facilities for the health department in addition to general hospital provisions. A new milk ordinance provides that all milk must come from tuberculin tested cows, and that all milk except certified and guaranteed raw milk must be pasteurized.

During 1929 there were 11 cases of diphtheria, but there have been no deaths from this disease in Palo Alto since 1921, and but 1 death since 1911. Toxin-antitoxin was furnished to immunize 310 persons, and 6 diphtheria carriers were discovered and isolated. At the end of 1928, 10 cases of tuberculosis were known to exist in the city and 12 new cases were reported during the year 1929 with 8 deaths. Expenditures in 1929 by all agencies for public health work totalled \$17,422, of which \$12,892 was expended through the health department, the remainder being provided by school boards, the Parent-Teacher Association, and tuberculosis scar sales. The allotment to health work in the Palo Alto city budget was 3.2 per cent of the total for all activities.

Racine, Wis.—Wisconsin's second city rates in the honor list of health officers' annual reports for 1929. This 64-page mimeographed report abounds in valuable statistical charts and tables and in enlightening descriptive text. The cost of 125 copies, exclusive of the time required in preparation by the regular staff, was \$73.11. There are a 1-page table of contents at the front and a 3-page alphabetical index at the back, which facilitate reference to special subjects.

A classified financial statement compares expenditures of 1929 with those of three earlier years and with appropriations for 1930. For purposes of comparison of the data of the current year with previous experience, figures are presented in tables for the first and last years of the health officer's incumbency, plus the median for the 5-year period. The *Appraisal Form* of the American Public Health Association has been effectively used in the evaluation of practices and services.

Plans have been completed for a new city hall in which the health department will be conveniently housed according to plans drawn by the health officer and accepted by the administration. The milk ordinance in the city was amended during 1929 to provide for compulsory pasteurization of all milk except certified.

A centralized family file has been established in which are recorded all data pertaining to a given family, such as birth, death, marriage, contagious disease, school physical examination, clinic attendance and any other contact which might be had with the health department. The estimated number of families in Racine is 15,000, and the new family file contains nearly 9,000 family records as a result of the first year of its service. Such a broad basis of contact with the people indicates that the health department is directly serving a large percentage of the citizens.

The most important new project of the year was the launching of a campaign for the examination of preschool children within 4 months before entering school. This campaign was headed by the American Legion through a committee of which the health officer was chairman. In addition to the Legion and auxiliary, the participants in this project were the American Red Cross, the County Medical Society, the public schools, the Catholic parishes, and pa-

rochial schools and the Junior League. The Medical Society sponsored 19 special clinics served by physicians appointed by the president, assisted by health department nurses. The health officer personally examined children at the city hall and the Red Cross opened its baby clinics to assist in the work. Over one-third of the 900 children invited for examination responded, 332 were examined thoroughly, and 52 qualified for Blue Ribbons presented by the Legion at a party at which the Legion auxiliary members were hostesses. All records were made available to the school which each child entered in September. One result of this project was an improvement in the *Appraisal* score for preschool hygiene from 34 points in 1928 to 60 points in 1929.

Ottawa, Canada—One of the most important factors in the 1929 report is the account of the epidemic of poliomyelitis which began in July and lasted until October. There were 176 cases with only 4 instances where 2 cases were reported from the same premises. The weather was dry, the rainfall being below the average. The treatment with convalescent serum was found to be effective.

The report shows the population for 1929 to be 125,496, with a general death rate of 12.26, which is higher than last year, and a birth rate of 23.84, which is the lowest rate yet recorded. The increase from 104.01 as in 1928 to 118.6 in infant mortality rate accounts for 20 per cent of all deaths. The chief cause of infant deaths was respiratory disease.

There was a reduction in the tuberculosis rate to 59.9 per 100,000, 78 per cent of the deaths being from pulmonary tuberculosis. The cancer rate increased, causing 8.83 per cent of all deaths. An excess of measles was due to an epidemic in February with 786

cases. The total incidence of measles was 1,907 cases for the entire year.

Vienna, Austria—An interesting report has been submitted of the dental work that is being done in the schools of Vienna by the 15 dental clinics for public school children, and 3 for institutional children serving 16 districts. This program was begun in 1922.

Each clinic has an operating room, a waiting room for children and one for the escorts of the children. It was found that the children were less nervous if they were kept together where they could play and amuse themselves before the examination.

There are 37 dentists and assistants giving services, each dentist making about 20 examinations a day. The entire program is under the supervision of a chief surgeon, who reports monthly to the municipal Board of Health and a head nurse who is in charge of all supplies. The maintenance cost for 1929 was \$63,234.00 and the budget required for 1930 will be \$72,171.00.

The children are given an examination and treatment twice a year up to the 14th year of age, and then advised as on their dental care up to 18. If a child can be examined he must, ~~con-~~ with the consent of his parents; if their consent is withheld he is excluded from the clinic. Before beginning an operation each child must brush his teeth under the supervision and instruction of the nurse. The sum total of children being cared for by the school dental clinics was 55,415 with probably 64,000 in 1930.

Sacramento, Calif.—The report for 1929 shows a marked increase in epidemic meningitis, 80 cases with 38 deaths against 15 cases with 8 deaths for 1928. There was also an increase in pneumonia and heart disease but a

slight decrease in cancer and in infant mortality, from 67.5 to 63.8. The birth rate was practically the same as last year. The city clinics rendered 12,633 services including 4,000 treatments for syphilis and an immunization serv-

ice of 2,697. The attendance at the health center showed a slight decrease over last year due perhaps to the establishment of the Sacramento Hospital Well-Baby Clinic, for babies born in the hospital.

UNIVERSITY OF FLORIDA

THE University of Florida, Gainesville, Fla., offered for the first time this year a Short Course in Water and Sewage Treatment from April 8 to 11. For this course the university has been fortunate in obtaining on its faculty state and government officials, engineers, water works officials and others prominent in the fields of water and sewage treatment.

KENTUCKY

THE Governor of Kentucky has appointed the following to the State Board of Health, and their appointments were confirmed by the Senate of Kentucky on March 20, 1930: Dr. E. M. Howard, *President*, Dr. A. T. Mc-

RESEARCH FELLOWSHIPS

THE National Tuberculosis Association announces a limited number of fellowships in social research as related to tuberculosis, open to graduate students who have had special training in statistics, social science or public health. Preference will be given to candidates who are interested in pursuing research in public health after the completion of this fellowship.

The fellowship grants will date from the beginning of the academic year in the fall of 1930. They are for a twelve-

month period and the fellowship grant amounts to \$1,500 for that period with a month's leave for vacation.

Interested candidates should write to Jessamine S. Whitney, Statistician, National Tuberculosis Association, 370 Seventh Avenue, New York, N. Y., for further information.

DR. WELCH HONORED

DR. William Henry Welch, professor at Johns Hopkins University and known as the "Dean of American Medicine," was honored by the medical profession on his 80th birthday, April 8. Many of his friends and former students met in Washington where a celebration was held. A portrait of Dr. Welch was painted by Alfred Hutty especially for this occasion. A souvenir volume will be published containing an account of the celebration. He was president of the American Social Hygiene Association in 1917, and is now honorary president and chairman of the General Advisory Committee of that association.

MR. DINWIDDIE IN NEW YORK HEALTH DEPARTMENT

CCOURTENAY Dinwiddie has accepted an appointment as Consultant to the New York City Department of Health, for the current year, for the purpose of making a study of conditions and needs in the child hygiene field.

DELTA OMEGA

LECTURES under the auspices of local chapters of Delta Omega, the honorary public health society, were given in March at the Massachusetts Institute of Technology and the Yale School of Medicine. At the third annual Delta Omega lecture at the Massa-

chusetts Institute of Technology on March 4, 1930, C. C. Young, Ph.D., Dr.P.H., of the Michigan State Department of Health, national president of the society, spoke on "The Trend in the Development of Public Health Laboratories." The speaker at the Yale School of Medicine on March 14, 1930, was George H. Bigelow, M.D., Dr.P.H., State Commissioner of Public Health of Massachusetts, who discussed the official program for cancer control in his state.

DEATH OF HENRY ALBERT

HENRY Albert, M.D., F.A.P.H.A., Health Commissioner of Des Moines, Ia., died on April 7, from a heart attack following an operation for appendicitis.

Dr. Albert was chief of the pathology and bacteriology department of the University of Iowa, and later director of the State Hygienic Laboratory, before becoming Health Commissioner in 1926. He was 52 years old.

SCARLET FEVER CASE

THE long expected suit for patent infringement by Dr. George Dick and Dr. Gladys Dick of Chicago, vs. the Lederle Antitoxin Laboratory of Pearl River, N. Y., is being heard in U. S. District Court for the Southern District of New York, by Judge Caffey (April 16). The Dicks are suing for patent infringement, claiming infringement on 7 of the 10 patent claims. The defense maintains that the patent for Scarlet Fever Toxin and Antitoxin is invalid because of lack of originality, and being developed from prior art. The case will be heard for the next 10 days or 2 weeks, experts being called from all parts of the country to testify both for the plaintiff and the defense.

PERSONALS

PAUL B. BROOKS, M.D., Deputy Commissioner of Health of New York State, has been reappointed to that position by Dr. Parran, Health Commissioner of the state.

DR. TALIAFERRO CLARK has been appointed to the position of Chief of the Division of Venereal Diseases of the U. S. Public Health Service, by Surgeon General Cumming. This position was left vacant by Dr. Thomas Parran who is the new Health Commissioner of New York State.

DR. ANDREW WEBSTER VAN SLYKE of Coxsackie, N. Y., has been the Health Officer of Coxsackie for fifty consecutive years.

GRACE GEORGE was recently appointed to supervise the health education work of the division of child hygiene of the Illinois State Department of Public Health.

DR. ALBERT CRUM BAXTER of Springfield, Ill., was appointed by the Governor to the position of assistant director of the State Department of Health.

THOMAS G. HULL, PH.D., Chief of the Division of Laboratories of the Illinois State Department of Health, has joined the staff of the American Medical Association in Chicago, leaving the State Department on April 1, 1930.

SURGEON GENERAL H. S. CUMMING of the U. S. Public Health Service, Director of the Pan American Sanitary Bureau, was recently made an honorary member of the National Academy of Medicine of Mexico, located in Mexico City.

In October, 1927, Dr. Cumming received a similar honor from the National Academy of Medicine of Peru, and he has lately been made an officer of the Order of Finlay, of Cuba.

CONFERENCES

May 7-10, National Tuberculosis Association, Memphis, Tenn.

June 2, week of, American Water Works Association, St. Louis, Mo.

June 6-14, National Conference of Social Work, Boston, Mass.

June 12-14, Western Branch of American Public Health Association, Salt Lake City, Utah

June 18-19, State and Provincial Health Authorities of North America, Washington, D. C.

June 20-21, Conference of the Surgeon General, Washington, D. C.

FOREIGN

June 21-28, Royal Sanitary Institute, 41st Congress and Health Exhibition, Margate, England

Aug. 3-9, Second International Congress for Sex Research, London, England

Aug. 4-9, International Veterinary Congress, London, England

Cancer Death Rates, Smoke and Topography

JEROME MEYERS, M. D.

Department of Health, New York, N. Y.

THE purpose of this paper is to draw more intensive attention of vital statisticians, of city, county, state and federal health agencies, and of other organizations concentrating on cancer problems to the possibilities for research in the variations in cancer mortality statistics, and to urge a wide, national study of such on the lines of the program here given. Clinical, experimental and post-mortem investigations of cancer have proceeded for decades; at times medical investigation needs a new and different approach to overcome a certain transmitted inertia, a new *point d'appui*. It is not claimed that smoke accounts for all cases of cancer; it is probably one of many causes, or one manifestation through biochemical irritation of some great underlying cause that is as yet beyond our ken. But who knows, if we can touch the fringe of the problem, that we shall not through some clue obtained penetrate the veil? No one man can easily take upon himself the burden of such cancer study as outlined. It is the work of a body of expert topographical engineers, meteorologists, chemists and biochemists, sanitary inspectors, field workers, and medical men.

That cancer death rates vary greatly in different countries is fairly well recognized. They will of course naturally be higher in populations containing a large proportion of persons in the older age groups, for the disease is one which affects chiefly those over 50 years of age. For this reason, in any study of cancer prevalence it is insufficient to deal with crude death rates; it is necessary to adjust the rates for the age and sex composition of the population. Even when this is done, however, considerable variations are discovered. It is usually not appreciated that the adjusted rates differ materially in the different

states in this country, and that they often vary widely in contiguous cities or parts of cities.

In 1920 the adjusted cancer death rates¹ (age and sex allowed for) for the 4 states in the country with the highest rates: Massachusetts, 97.9 per 100,000; Connecticut, 92.9; New York, 92.5; Minnesota, 92.1; show a considerable divergence from the 4 states having the lowest rates: Tennessee, 51.6; North Carolina, 49.7; Mississippi, 48.0; and South Carolina, 45.8. The refined rates (adjusted for age, sex, and residence of the deceased) for cities for 1924 show very marked differences not only between different cities in the country, but between cities in the same state, and even between nearby cities.² San Francisco has a rate of 133.1; New York City, 121.4; Albany, 107.2; and San Antonio, 73.0. Two adjacent cities are Minneapolis and St. Paul; the former's rate is 98.1, the latter's 120.9. The rate of San Francisco is 133.1, that of nearby Oakland is 92.7. The rates of the different boroughs of New York City are: Manhattan, 145.7; Bronx, 124.2; Brooklyn, 104.3; Queens, 106.7; and Richmond, 106.4. What are the importance and meaning of such variations in the complex etiology of cancer?

C. E. Green,³ as a result of investigations in Scotland and England, showed some marked differences in the death rate from cancer even in comparatively small areas. In Scotland he found rates running from 17.6 per 100,000 in Kinsing Park, a suburb of Glasgow, to 97.3 in the rural districts of Nairnshire. In London he states the rate is 1-7 for all deaths in the Strand district, while, in Stepney, it is only 1-54. He also found that in the County of Nairn, where there was the highest death rate, there was one area of 100 square miles with 1,000 inhabitants where he could obtain the record of only 1 case of cancer, a rodent ulcer. He further points out that the rate in the Orkney Islands was generally low, but that three islands, where peat approaching the composition of coal was used, showed a high rate. He also calls attention to the known facts that epithelioma is very prevalent among chimney sweeps who show the highest rate for any occupation, also among gardeners or farmers who use soot, and that cancer is known to be frequent among workers in aniline dyes, paraffine, and gas pitch, brewers and metal workers who use sulphuric acid. His theories as to the causes of the variations in cancer death rates are:

1. Where the death rate is low we have a low or high area comparatively flat or at most with low swelling undulatory hills with houses built on the sides, whereas those sections with a high mortality are intersected by gulleys or valleys with houses in the hollows, or the whole section is in the hollow or cup or depression surrounded by higher land.

2. The excessive presence of SO_2 gas from the use of coal with a high sulphur

content was present with the highest incidence of cancer. In all the Orkney Islands except three the death rate is very low. Peat is used in all the islands. In the three islands with high rates, it was found on analysis that the peat used had 0.75 or more sulphur, approaching the sulphur content of coal.

3. Uneven roof-lines such as we find in the Strand district with its death rate of 1-7 cause poor house or chimney ventilation with an increase of SO_2 while a level roof-line as in Stepney with a rate of 1-54 affords opportunity for excellent ventilation with little accumulation of SO_2 .

Additional data to support Green's theory of the relation of combustion products to cancer are found in his article⁴ published in 1915. They are based on maps by J. Bertillon,⁵ who states that, if a line be drawn from La Rochelle to St. Etienne and from there to the Rhone, the Pyrenees and the seas, the area does not contain a single department where cancer is frequent, whereas, in every department inside a square made, having the sea on the west and lines from Caen to Angers, Angers to Dijon, Dijon to Mézières, cancer is highly prevalent, the death rate per 100,000 being four or five times as great as that in the square territory in the south. Each square comprises about one-third of France.

Bertillon confessed that he could give no adequate explanation of the great differences in these cancer death rates. Green then sent a questionnaire to the prefect of each of the departments of France, asking information as to the form of fuel used in his territory. He found that in the northern square or area, where the rates were high, coal was used, while in the southern area wood was burned. Even in the north in Brittany the rates were low and here wood was used. Green concludes:

Some other element than strictly sulphur content may be involved in the relationship of certain fuels to cancer death rates of the districts in which they are used. Some chemical condition of the fuel, its ash, or its other products of combustion, may be responsible.

It should be noted that by smoke is meant not only the contained solids such as tar and carbon, but the invisible gases also. The amount of tar in smoke is indicated by estimates that 500,000 tons of tar are released yearly above England by the combustion of coal. The production of cancer by the application of coal-tar to the skin of rabbits and mice by Yamagiwa and Ichibawa, and a long line of other workers needs no amplification. Passey and Carter-Braine⁶ have succeeded in producing epithelioma in white mice with an ether soluble product of soot from a bituminous coal. Kennaway,⁷ working on the relation of coal and oil combustion products to cancer, summarized his work on gas-works tar by stating that the industrial evidence, supplemented by the experimental also, shows that the cancer producing

substance is present in the higher boiling fractions; namely, creosote oil, anthracene oil and pitch; and hence may distil over through an interval of temperature extending roughly from 250 to 500° C. He concludes his work on cancer produced by gas-works tar, lignite tar and shale oil:

Thus the attempts made as yet to find the cancer producing substance among the well known constituents of coal-tar have given wholly negative results. It is not unlikely that this substance is a compound, as yet unknown, which is unstable and present in amounts so small as those of the vitamins in foods; as in the case of some hormones its identification may be long delayed even when very concentrated preparations may be obtained.

Most interesting are certain figures recently published by the registrar general⁸ of England. They show a possible relation between cancer and certain occupations and fumes from fuel combustion. For the decennium ending 1927, the 3 occupations showing the greatest incidence of cancer of all sites were (1) the china kiln and oven men, (2) the puddlers, and (3) the gas stokers. Particular attention must be drawn to the fact that all of these workers are exposed to gases and fumes. In the work of cotton spinners who rank fifth in frequency of cancer, shale oil (shale is a low form of coal), regarded as the most dangerous of all oils in its cancerogenic properties, is used.

Based on Green's theory of smoke and topography, a survey⁹ of the Borough of Richmond, or Staten Island, one of the five boroughs of the City of New York, was begun by the writer in 1920 under the New York City Department of Health, Bureau of Industrial Hygiene, and was published in abridged form in 1928 by the department.¹⁰ Staten Island, $13\frac{1}{2} \times 7\frac{3}{4}$ miles, is peculiarly adapted to such an investigation, as it presents varied hilly and level areas, and part of its northerly shore, separated only by the comparatively narrow Kill van Kull from Constable Hook, Bayonne, and Bergen Point, N. J., has been exposed for many years to the smoke and fumes from manifold chimneys and stacks of at least twenty-five great industrial, metal refining, chemical, and oil refining plants. The island was divided into 13 districts, and each intensively studied for the factors of smoke from industrial plants and dwellings, topography, meteorology, racial composition, age, and sex. The refined cancer death rate average for the years 1914-1920 inclusive was calculated for each district. Only cases resident at least 3 years before death were included. This is the first time in any cancer study that the time factor and locality were taken into consideration in the possible etiology. No cases in institutions for the aged were included. Proper allocation was made for all other borough deaths.

The corrected weighted average annual death rate varied from 42.1 to 78.9 per 100,000. The probable error for each district, estimated by Arne Fisher, showed their reliability. The following conclusions were drawn:

1. There is a marked and interesting variation in cancer death rates in different countries, within countries and states, and probably even in different sections of cities.

2. On Staten Island, individual or parent nativity does not alter our corrected death rates. In mixed populations, differences in cancer death rates among Irish, German, English, Italian, and natives tend to neutralize each other. Diet also was found of no great moment.

3. On Staten Island there may be an etiological relation between the incidence of cancer and topography, open level districts, of high or low altitude, showing lower cancer rates than land in hollows or depressions or intersected by gullies, valleys or lying against adjacent hills. Albany and San Francisco should make interesting studies.

4. There may be an etiological relation between the combustion products of coal and oil and cancer. Those sections of Staten Island exposed to smoke, fumes, and gases show a higher cancer death rate than those not so exposed. House-heating and chimney ventilation are also important, as gases and fumes from these sources may bear a relation to cancer incidence as found in our districts.

5. The better combustion of fuels in industry and homes, or absorption of gases, smoke and fumes to avoid atmospheric or room contamination, may mean less cancer.

6. Whatever may be the possible errors in this study of a comparatively small number of cases (515), it cannot fail to show even on an island $13\frac{1}{2} \times 7\frac{3}{4}$ miles, divided into 13 districts, variations in cancer death rates, and these variations would seem in the light of our findings to bear a relation to etiological factors of fuel and topography. These conditions therefore would seem to be a part of the complex etiology of cancer.

Along the lines of the above study, I have been investigating three sections of Manhattan, each comprising 6 sanitary districts, one on the lower east side, one on the lower west side, and one along Central Park West. In the first two are largely old tenements with room heating by stoves, in the third, high class private houses, apartment houses, and hotels with central heating by steam or water. A period of at least 5 years will be covered and will include no case that has not been resident at least 3 years before death. Final figures for population must wait for the 1930 census.

There is available at present more than one such problem crying for study and elucidation. To refer again to the refined cancer death rates given for 1924—why has St. Paul a rate of 120.9 and Minneapolis one of 98.1? Here are two contiguous cities, apparently with a similar racial composition, where medical facilities for diagnosis and consultations cannot greatly differ, with a variation in rate that is

striking. Recently the writer, while in Minneapolis at the cancer program of the American Public Health Association, made a crude topographical survey of these two cities. It was noted that Minneapolis is very flat while parts of St. Paul are distinctly hilly with other sections directly under the hills. Can smoke and fumes and gases from industries and homes and topography play a part? Attention is called to the rates of Oakland and San Francisco; the former, 92.7, the latter, 133.1. Why? Is it because San Francisco is exceedingly hilly or Oakland flat? Are there racial differences?

Hoffman's recent work on San Francisco¹¹ shows not only high general cancer rates but also high rates for cancer of separate organs, as compared with general United States rates. Why? In New York State the rates vary from 121.4 for New York City, with 145.7 for the Borough of Manhattan, to 98.2 for Syracuse. Albany, with a rate of 107.2, practically all hills and depressions and lying in a great cup or depression and exposed to much smoke, offers an ideal city for cancer study in relation to smoke and topography. Why are the rates in New Jersey—Jersey City 129.7, Paterson 110.9, Trenton 100.1, Newark 97.8, and Camden 86.5? Why are they in Texas—Houston 92.9, Dallas 84.7, and San Antonio 73.0? Why in Houston is the rate for colored 69.0 while in Dallas it is 114.3? Why in Connecticut is New Haven 115.1 and Hartford 96.2? New Haven and Syracuse each has medical colleges; the first has a rate of 115.1, the second 98.2. Why in Missouri is the rate for St. Louis 107.4, while that of Kansas City is 91.1? Why in Pennsylvania are the rates—Philadelphia 108.6, Pittsburgh 106.1, Reading 90.1? There must be some explanation other than the factors of age, sex and allocation already considered.

As was pointed out in Staten Island, even after a study by such writers as Hoffman,¹² Willcox,¹³ H. G. Wells,¹⁴ and H. Green,¹⁵ it would seem that even with due allowance for better diagnosis, better vital statistics, concentration of physicians, and increased longevity, there remain other factors to be considered. Even if one half of the increase of cancer deaths is explainable by the above factors, still in this half the question of environmental conditions as topography and smoke may be of importance. The other half of the increase, concerning which Willcox after exhaustive analysis is not certain, would also be affected by such factors. And even if the entire increase was thus explained, it would not mean that environmental and racial factors did not cause cancer death rate variations. It would seem that the number of doctors, diagnoses, vital statistics, and longevity should not be so diverse in these cities within one state. In fact, H. Green¹⁶ states that the unsatisfactory correlation of the number of physicians

to the cancer death rates of the cities he studied can be explained by the fact that there are sufficient physicians in each of these cities.

It is only along the lines of the Staten Island study, taking into account age groups, the elimination of non-resident deaths, topography, and housing and industrial conditions, that any final conclusions would be warranted.

It would seem that a closer and truer view of cancer factors can be obtained from a study of a small compact area divisible into districts than from a consideration of states or countries. In a borough such as Staten Island, divided into contiguous districts in which we can study comparative cancer death rates, there cannot be great differences in medical and surgical diagnosis, or in reporting cancer deaths. Moreover, in such an area the physicians and surgeons see and diagnose patients from various districts. H. G. Wells¹⁶ stresses the pitfalls of cancer diagnosis and statistics but finally says:

At present, it seems to me, the most that we can say is that although all races and groups of human beings are susceptible to cancer, it is probable that conditions of life and hereditary constitutional factors modify the frequency with which cancer appears in different races and different nationalities or the frequency with which it attacks different organs and tissues.

Lombard and Deering¹⁶ have recently published a study of cancer mortality in nativity groups which should point the way for similar studies by health organizations. They report, among other findings, that the foreign born in Massachusetts have sufficiently good diagnosis to eliminate that factor in discussing the high cancer death rate in their case. Such important studies are but a part of the scheme of cancer investigation entailed in a comprehensive cancer survey.

A plan for such a survey is as follows:

1. Division into topographical districts of a city or adjacent cities by a topographical engineer with preparation of maps
2. Listing by districts, street and number all cancer deaths resident at least 3 years before death, and proper allocation to and from the districts with elimination of all non-resident deaths and all institutional deaths
3. Meteorological study of the prevalence and direction of winds and barometric conditions
4. Study of atmospheric contamination by the combustion products of coal, oil or wood:
 - a. From industrial plants
 - b. From domestic houses using (1) coal stoves, (2) wood stoves, (3) central heating, hot air, hot water, steam, (4) oil furnaces
5. Study of coal, wood and oil consumption
6. Study of occupation of deceased
7. Study of nativity and nationality
8. Study of diet

9. Density of population
10. Blood studies, reaction, composition
11. Study of chemical and possibly radioactive constituents of smoke
12. Refined cancer death rate in each district and probable error
13. Discussion of all factors and conclusions

SUMMARY

1. There is a variation in cancer death rates between countries, states, cities, even adjacent, and very probably between parts of cities.

2. Green's work in England and Scotland and Bertillon's figures for France would seem to point to a distinct influence of topography and of combustion products of fuel on cancer death rates.

3. The Staten Island cancer study along the lines of Green's theories, but allowing for age, sex, nativity, nationality, diet, allocation, exclusion of institutional deaths, and a 3-year period of residence before death, points to a relationship between smoke and fumes from industrial plants and homes and topography and cancer prevalence.

4. Other statistical, chemical, and experimental data point to the influence of smoke and fumes or tar on cancer. What the action and nature of a cancerogenic factor liberated by combustion are is not certain. Whether such factor is chemical or possibly radioactive in nature is material for other studies.

5. Further studies like the Staten Island investigation should be made by city, county, state or national health bodies, or cancer organizations. This means a corps of experts in a number of fields. The burden of such a study is too great for a single worker.

6. Further studies are now indicated and offer a rich field for an advance in the knowledge of the etiology of cancer in the case of (1) Minneapolis and St. Paul, (2) San Francisco and Oakland, (3) Albany, N. Y.

WAIKIKI BEACH, HONOLULU

Health and Welfare in Honolulu, Hawaii

FREDERICK E. TROTTER, M. D., AND IRA V. HISCOCK, F. A. P. H. A

President, Territorial Board of Health, Honolulu, Hawaii; and Associate Professor of Public Health, Yale School of Medicine, New Haven, Conn.

HONOLULU, located on the island of Oahu, is the principal city and seaport of the Territory of Hawaii. The islands making up the Territory* abound in natural beauty, human resources, and unusual and fascinating phenomena, and are often called the "Paradise of the Pacific." They are of volcanic origin with minor coral additions. Oahu's volcanoes are all extinct. These islands lie more than 2,200 miles from their nearest land neighbor, California, 3,400 miles from Japan, and 4,410 miles from Australia. The land area of the islands covers 6,454 square miles, while the island of Oahu occupies 598 square miles and the city of Honolulu 25 square miles.

Honolulu has a subtropical climate, with even temperature (average 74.7° F., with extremes of 60° to 85° F.) and more than the usual sunshine, providing life out of doors throughout the year. The atmosphere is less humid in the morning than in the evening. Averages of the yearly mean for 24 years showed readings in relative humidity at 8 A.M. of 68 per cent, and at 8 P.M. of 71 per cent. The city rainfall varies from an average of about 20 inches per annum at

* The islands most highly developed are Hawaii, Maui, Kahoolawe, Lanai, Molokai, Oahu, Kauai, and Niihau.

Waikiki and along the harbor front to about 150 inches in the upper Manoa and Nuuanu valleys, so that one may enjoy either a wet or a dry climate without leaving the city.

Honolulu is a modern American city of medium size. The population* (113,000 in 1928) is greatly diversified as to race, the Hawaiian and Oriental groups figuring prominently. The Territory of Hawaii, on its own petition, entered the American Union in 1900, having for some three-quarters of a century previously experienced the influence of American education, religion, and commercial practice. All immigration laws of the United States are therefore applicable in Hawaii, which has become a "melting pot" of races and nationalities, with relative freedom from racial prejudice.

Honolulu is an educational center for the Territory, being the seat of the University of Hawaii, the normal school, Punahou School, and other important institutions. Hawaii is of strategic importance from a military and naval standpoint† as well as for political and commercial reasons. Cane sugar and pineapples are the main products, although coffee also figures prominently as an export. The tourist business is developing rapidly with improved steamship facilities in the Pacific.

In 1927, there were 98,800 employees and their families living in houses provided by 42 plantations, accounting for nearly one-third of the population of the islands. A total of \$659,800 was expended that year by the plantations for new dwellings, \$653,629 for rehabilitation, and \$795,392 for medical, nursing and sanitation services. Several plantations have modern and fully equipped hospitals, including dispensary and visiting nurse services. The chiefs of the medical services are also local representatives of the Board of Health. The pineapple canning factories likewise maintain modern dispensaries, medical and nursing services.

PUBLIC HEALTH

Responsibility for public health work in the city and county of Honolulu is divided between the Territorial Board of Health and the City and County Board of Supervisors. Certain activities, such as much of the public health nursing, dental treatment and child hygiene, as well as clinics and recreation, are carried on at Palama Settlement,‡ while the Department of Public Instruction is largely responsible for

* Population of entire Territory in 1928, 348,767; population of Oahu, 180,000.

† On the island of Oahu are several important Army posts, including Schofield barracks, the largest Army unit in the United States, and an important Navy station at Pearl Harbor, adapted for expansion as needs arise.

‡ Chiefly supported by the United Welfare Fund, the City and County, the Chamber of Commerce, and by endowment, including the Strong Foundation (dental treatment).

OUTRIGGER CANOES, HONOLULU HARBOR

dental hygiene and nutrition work among grade school children. Voluntary agencies engaged in special activities of a public health nature include, besides Palama Settlement, the Free Kindergarten Association, the Junior League, the Parent-Teacher Association and various welfare agencies. The Chamber of Commerce has a public health committee and is building up a reserve fund of \$250,000 for use in the event of an epidemic. The United Welfare Fund raises \$450,000 each year for the work of welfare agencies; and a part of this amount is allocated for health work and the care of indigent sick, exclusive of hospitalization.

The Territorial Board of Health, unlike most state boards of health, carries the heavy responsibility of hospitalization of cases of leprosy, mental disease and tuberculosis. The funds and organization of the city and county health department are devoted almost wholly to the care of indigent sick in hospitals or homes, and are adequate to permit of only milk and food inspection work. The 1928 expenditures by all agencies, in the city of Honolulu, for public health work amounted to \$1.96 per capita, while over three times this amount was spent for the care of the sick. The total expenditures of the Board of Health in the whole territory amounted to \$1,222,288.

The physicians of the county have an active medical society which holds regular meetings and coöperates in public health activities. The society aided in the preparation of a communicable disease control code. In 1929 the County and Territorial Medical Societies actively coöperated with the Board of Health in a toxin-antitoxin immu-

nization campaign which resulted in the protection of some 90 per cent of the school children and 40 per cent of the preschool children. At the Queen's Hospital, once each week, for an hour, is held a valuable clinical-pathological conference which is regularly attended by 40 to 75 of the leading practitioners of the county. Palama Settlement, the principal voluntary health organization, has a strong medical advisory committee of which the President of the Territorial Medical Society is chairman, and the President of the Board of Health, an ex-officio member.

The collection and analysis of vital statistics are conducted by a special bureau of the Board of Health. In 1928, in Honolulu, a resident birth rate of 39.7 and a general death rate of 14.7 were recorded, with an infant mortality rate of 63.98. For rural Oahu, the infant mortality rate was 102.4. The principal causes of death were tuberculosis (222.3), pneumonia (209.5), heart disease (155.5), nephritis (126.6), cancer (91.3), and diarrhea and enteritis (87.5), while diphtheria accounted for a specific rate in the city in 1927 of 22.3, and automobile accidents for a rate of 20.5. Death rates from tuberculosis and heart disease were nearly three times as high, and from pneumonia and diarrhea and enteritis over twice as high, for the Hawaiians and Filipinos as for other race groups. The figures for broncho-pneumonia were over twice as high as those for lobar pneumonia. Deaths from non-pulmonary tuberculosis have decreased considerably since 1924, as a result of increased use of pasteurized milk and the systematic tuberculin testing of dairy herds.

It is chiefly necessary to provide a well rounded program of local control, and then to watch incoming ships to prevent the spread of communicable diseases. On the mainland, on the other hand, each state is subject to visitors from 47 other states, and adjoining countries, in addition to the ships which enter many ports. In Honolulu, the U. S. Public Health Service maintains medical officers and a quarantine station, and coöperates with the Board of Health, in this work and in the control of leprosy. Hospitalization of city cases of communicable diseases is carried out in the isolation wings of 3 general hospitals and the Children's Hospital. During 1929, some 14,000 children (approximately 4,000 under 5 years of age) received three immunizations of toxin-antitoxin. Vaccination of school children against smallpox is compulsory.

The venereal disease services in Honolulu are very limited; but one clinic is maintained. Reporting of cases is not required although the Board of Health has endeavored to secure the necessary legislation for reporting by name and address. Some education in sex hygiene

has been carried on in the high school, and in Kamehameha school for Hawaiian children.

The tuberculosis service is primarily a responsibility of the Board of Health, through a separate bureau with a full-time director, and its division of public health nursing. Sanatorium facilities are provided at Leahi Home which operates under its Board of Trustees, and receives the major portion of its revenue from county and territorial subsidy. There are 4 clinics each week in the city, with clinics once in 6 weeks in each of 7 localities of the rural area. Reporting of tuberculosis cases is fairly satisfactory. Last year there were 420 patients registered in the city at clinic for diagnosis, who made 3,406 visits, and this service is increasing under capable supervision. Emphasis is given to contact cases and practical use is made of X-ray facilities through a coöperative arrangement between the Board of Health and Palama Settlement. The greatest weaknesses are in the lack of preventorium facilities* and of sufficient nursing personnel. The Palama Fresh Air Camp cared for 153 undernourished children for 5 weeks each during the summer of 1928.

The Board of Health has a Bureau of Leprosy with a medical staff, and operates the Kalaupapa Settlement on Molokai, Kalihi hospital which is a receiving station on Oahu, the Kapiolani Girls' Home, and the Kalihi Boys' Home for non-leprous children of parents who have the disease. On Oahu there were 41 cases of leprosy reported in 1928, while 44 cases were reported in the territory with 51 deaths.

During 1928 in Honolulu there were 4,496 live births to resident mothers. Of this number, 649 occurred in hospitals, 427 in maternity homes, 710 in homes attended by physicians, 1,431 (chiefly Japanese) in homes attended by midwives, and 1,414 (chiefly Japanese, Hawaiian and Chinese) in homes attended by "others," such as friends or members of the family. Palama Settlement has 3 prenatal and 12 well baby conferences, and maintains a nursing service for prenatal, obstetrical, infant and preschool child care. Excellent progress is being made in infant welfare work in the city, although the intensity of nursing service falls somewhat below the desired standard. In the rural districts, the Board of Health holds regular child hygiene conferences in coöperation with the plantations.

Honolulu has 39 public schools, including a normal school, a high school, 6 junior high schools, a school for the deaf and blind, a vocational school, and an opportunity school. In addition there are 42 private and parochial schools, including the kindergartens. The en-

* Provision has been made for the opening of a preventorium at Palama Settlement in July, 1930, through the coöperation of Palama, Leahi Home, the College Club, and other agencies.

tire school registration totals 28,632 in public schools, and 8,285 in private and parochial schools.

The responsibility for school health supervision rests with the Board of Health and the Department of Public Instruction, the former providing medical and nursing care, and the latter dental hygiene, nutrition and physical education. Dental treatment of school children of needy parents is provided at Palama Settlement by the Strong Foundation where 5 full-time dentists are employed. A joint school health committee has recently been formed, made up of representatives of the Board of Health and the Department of Public Instruction.

Public health nursing was originally supplied by Palama Settlement, the first nurse having been secured in 1906. Now the Board of Health employs, for work in Honolulu, 7 nurses, and Palama Settlement employs 22 nurses. There is a ratio of 1 visiting nurse to approximately 4,300 persons. Recognizing the need for economic service and the importance of emphasis on the problems of the family as a whole, the nursing personnel of these two organizations has recently been pooled on a generalized district basis. The director of the Board of Health nurses is the supervisor of field work, and the director of the Palama nurses is chiefly responsible for administration. Heretofore, the Palama nurses did prenatal, obstetrical, infant, pre-school, and bedside nursing, while the Board of Health nurses did school and tuberculosis nursing. A teaching center for public health nurses has been established at Palama.

All of the milk sold in the city is from tuberculin tested herds, and 65 per cent is pasteurized. Retail dairy farms (41) are inspected twice a month and pasteurizing plants (3) monthly or oftener. At present food and milk establishments are supervised both by the City and County and by the Territorial Board of Health, but it is anticipated that this work will soon be turned over to the latter body. Sanitation work is a function of a Bureau of Public Health Engineering of the Board of Health.

Diagnostic work in the city is handled through the Board of Health in a private laboratory, while food and water analyses are made in separate laboratories maintained in the Bureaus of Pure Food and Drugs and of Engineering. In addition, much diagnostic work is done in the hospital and clinic laboratories of the city.

Honolulu has demonstrated its understanding of modern welfare work. It is gratifying to note the high standard of effectiveness which characterizes the work of the United Welfare Fund, the Council of Social Agencies, the Central Child Placement Committee, and of many

welfare agencies in the city. It is believed that there has never been a more sincere and more careful effort sympathetically to serve a community need than is being exerted by the welfare agencies.

A comprehensive health and welfare survey of Honolulu was made in 1929 by the Committee on Administrative Practice of the American Public Health Association, under the auspices of the United Welfare Fund and the Territory of Hawaii. A strong advisory committee of the United Welfare Fund, including representatives of the medical society, is now studying the recommendations.* The Governor of the Territory has also appointed an advisory committee on Public Health to review the findings. One of the most important recommendations of the survey is that a plan be developed whereby all the public health work of an official nature in the city and county be carried on by the Territorial Board of Health, with a full-time, experienced medical health officer serving as deputy health commissioner of the Territorial Board, but in charge of the work in the city and county of Honolulu. Other urgent needs are for full-time trained medical directors of communicable disease control, child hygiene, and health education and for additional public health nurses.

* The report was submitted in October, 1929. By February, 1930, 15 of the 121 recommendations had been carried out and 21 others had been partially fulfilled. The follow-up on this survey by local authorities is a notable record of achievement.

GROUP OF CHILDREN, LEAHI HOME

Hydrogen Sulphide in Industry Occurrence, Effects, and Treatment*

W. P. YANT

*Supervising Chemist, Health Laboratory Section, U. S. Bureau of Mines
Experiment Station, Pittsburgh, Pa.*

MOST persons who have worked in a chemical laboratory think of hydrogen sulphide (H_2S) as merely a chemical reagent, offensive to the sense of smell when first encountered, later tolerable, and finally (as one would judge from the odor of laboratories) delightful to some chemists. No chemistry student and few instructors consider hydrogen sulphide to be particularly harmful. The reason for this is perhaps the neglect of authors of textbooks to stress the toxic properties of the gas, and usually, though not always, to uneventful experience with the gas when used in small quantities under good ventilation.

The knowledge that hydrogen sulphide is very poisonous is not recent. Details of poisoning by hydrogen sulphide reported¹ in 1785 are in good agreement with modern descriptions of this type of accident. The toxicology of hydrogen sulphide has likewise been known for a long time. Prompted no doubt by the occurrences of poisoning, investigations^{2,3} were reported in 1806 and 1827; these major findings are also in good practical agreement with the present accepted data.^{4,5,6,7}

The lack of general familiarity with hydrogen sulphide poisoning among industrial surgeons in this country has been due to the fact that until 10 or 15 years ago cases of poisoning were rather unusual and did not constitute a major industrial health hazard. Since then, hydrogen sulphide poisoning has become a major hazard in certain industries, and has not only demanded the attention of industrial surgeons interested in promoting health and safety, but also the attention of engineers planning industrial projects in which the gas might be encountered, because experience has shown that its presence can readily impede progress and increase costs.

Briefly, the principal sources of hydrogen sulphide of importance from the viewpoint of health are: Gypsum mines, sulphur mines and

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

wells, caissons and tunnels, natural gas, production and refining high-sulphur petroleum, sewers and other places where organic matter decomposes in confined spaces, blasting with black powder and other explosives in heavy sulphide ore, gas manufacture and low-temperature carbonization of coal, manufacture of chemicals, dyes, and pigments. In addition it is present in the water of some mineral springs, in rock fissure gases, volcanic gases, and arises from bacterial action in brackish waters. Some of these are associated with those previously mentioned.

The gas may be liberated direct from the original source or place where it is generated, or, due to its solubility in water and oil, may be transported great distances, then escape and create dangerous atmospheres at unsuspected places. Crude oil charged with hydrogen sulphide will tend to give off the gas from the time it leaves the well until it is refined. Waste water that has been in contact with hydrogen sulphide, as in petroleum refining and the production of sulphur from wells, will transport it to accessible places, or to the air of drains, sewers or other confined spaces from which it may find its way to places frequented by persons. In mines, tunnels, and caissons, its presence may be due entirely to the inflow of hydrogen sulphide bearing water from which it escapes into the air.

Hydrogen sulphide is not always a health hazard in all the occurrences mentioned, but has been found frequently enough to make it worthy of consideration when investigating injury or accident from exposure to gas, and in the designing of industrial and engineering equipment and projects where there is potential exposure. If consideration is not given, undue trouble and expense or even failure of the project may result.

Petroleum Industry—The most important occurrences of hydrogen sulphide poisoning are in the petroleum industry.^{5, 6, 7} They came as a concomitant of light Mexican petroleum, a type of crude oil which had a markedly higher sulphur content than those previously handled. Immediately, fatal poisoning and much trouble from eye, nose, and throat irritation occurred in practically all phases of the production, handling, and refining.

The presence of hydrogen sulphide was shown by the odor, blackening of white lead paint, tarnishing of brass fixtures and silver coins, but few persons associated these with that gas. The action was thought to be too rapid and deadly for a gas so commonly known. Accordingly, the idea became general that some highly toxic gas such as hydrogen cyanide, not previously identified with petroleum and natural gas, was present in this new type of crude oil.

As it was not generally known that hydrogen sulphide is practically as toxic as hydrogen cyanide, an investigation was undertaken, which showed that hydrogen sulphide was by far the most toxic gas encountered in these products.⁵ It was present in all places where accidents had occurred, and frequently in amounts many times greater than were necessary to cause almost instantaneous death. It was found in injurious quantities in practically every phase of the production, handling and refining of high sulphur crudes. Steam-still receiving houses and tanks containing finished gasoline were probably the only places where the possibility of hydrogen sulphide poisoning was negligible. Comparison of the physiological effects of hydrogen sulphide with cases of poisoning showed the action to be the same. No trouble was experienced when the hydrogen sulphide was removed or was absent.

Trouble from hydrogen sulphide in the petroleum industry has been markedly increased by the finding of large deposits of high-sulphur crude oil in the United States, principally in western Texas, and hydrogen sulphide poisoning now constitutes one of the major industrial hazards in this country. The gases encountered in the production of oil from certain fields contain as much as 10 to 12 per cent by volume of hydrogen sulphide, and 50 to 75 per cent has been found in refinery gases, whereas 0.005 to 0.01 per cent will cause conjunctivitis (gas eyes) after prolonged exposure, and 0.06 to 0.10 may cause almost immediate cessation of respiration, followed by death if rescue and resuscitation are not effected immediately. The difficulty of preventing accidents is further emphasized by a consideration of the magnitude of the industry, the number of persons employed, the conditions under which petroleum is produced, and the practical impossibility of preventing persons from coming in contact with the gas, either accidentally or in carrying out operations such as drilling-in, casing, making connections, gaging, and the many steps in refining, all of which present a potential exposure.

The accidents and troubles experienced recurrently are evidence of the dangers and the necessity of precaution. Men have been found dead on the open derrick floor, presumably caught by the first burst of gas when they drilled-in. During early experience with large amounts of hydrogen sulphide gas, when operations were conducted without respiratory protection, as many as 31 cases of unconsciousness were reported in closing-in one well, and in similar operations men have fallen into derrick cellars and sustained additional injury. Connection men have been overcome in ditches, and gaggers, sometimes so suddenly that they have fallen off storage tanks. Persons have

been fatally gassed by walking into ditches, ravines, and depressions in which the gas had accumulated. This danger is shown by the common occurrence of dead rabbits and birds around storage tanks, especially inside the fire walls. Men have been killed on entering tank ship compartments and storage tanks for the purpose of cleaning or repairing. At the refineries, fatal cases of poisoning have occurred at a wide variety of places. Men have been overcome while walking along a battery of batch stills; while repairing empty condenser cooling water tanks in which sewer connections were not closed; in pressure-still houses while attempting to close leaky valves; in pipe-line ditches; while gaging, and cleaning tanks.

Mild and non-fatal poisoning, in the form of conjunctivitis and moderate to severe irritation of the respiratory tract, shows the constant presence of the gas. Hundreds of these cases occur in the oil fields—in fact, some workers seem to think that gas eyes is something that goes with their particular job. Aside from discomfort and frequently intense pain, this degree of poisoning is not usually serious. There is, however, the always existing possibility of permanent impairment of vision or fatal complications from irritation of the respiratory tract. The economic feature is also important because the victims are incapacitated and require medical attention, and important development operations frequently suffer through lack of personnel.

Caissons, Tunnels, and Mines—The occurrence of hydrogen sulphide either as a constituent of rock-gas or dissolved in strata-water has been the cause of a great deal of trouble and a number of fatal accidents in caisson work, tunneling, and certain mining operations. The gas was encountered during the construction of the London tunnel under the Thames¹⁰ and is said to have constituted an obstacle which prolonged the time of building, and probably ultimately increased the cost by many thousands of pounds. In the United States it was met with in sinking caissons off the coast of Florida where it was necessary to cease operations until means were devised for taking care of the gas, and in similar work along the Great Lakes, at Detroit and Cleveland. At the latter places it is usually associated with methane.

Except through the use of black blasting powder, hydrogen sulphide rarely occurs in significant amounts in coal mines and metal mines, although dangerous quantities may be formed in the latter by blasting in heavy sulphide ores.^{11, 12} Dangerous amounts frequently occur in gypsum and sulphur mines.

Decomposition of Organic Matter—As a rule, the decomposition of organic matter, such as sewage, animal refuse, and the like, is accompanied by liberation of hydrogen sulphide, and if it escapes into

a confined space dangerous amounts will accumulate. Hydrogen sulphide poisoning from exposure to the gas in sewers has occurred repeatedly. It has been encountered at fat-rendering plants and tanneries.

Chemical Industries—In chemical industries, hydrogen sulphide may occur through its use as a reagent, as in the manufacture of sulphur chloride, barium carbonate, dyes, and pigments, or by its formation in processes such as are used in the manufacture of rayon.

TOXICOLOGY AND PHYSIOLOGICAL ACTION

Hydrogen sulphide has two apparent physiological actions—"subacute" and "acute poisoning." The former is a local inflammation caused by direct action of the gas, and perhaps some absorption products, such as sodium sulphide, on the tissues with which it comes in contact. Moist tissues such as the conjunctivae and lining of the respiratory tract are the significant sites of attack. "Acute poisoning" is the response of the nervous system to free hydrogen sulphide in the blood." The action on the nervous system is general, but in fatal poisoning the most important response is rapid respiratory paralysis. The possibility of subacute or acute poisoning is almost wholly dependent on whether the concentration is below or above an apparent threshold concentration—estimated about 0.07 per cent by volume.

The severity of subacute poisoning increases directly with the concentration of gas and duration of exposure. A long exposure to a low concentration will produce as severe poisoning as a shorter exposure to a higher, within, of course, the range for subacute poisoning. Subacute poisoning does not terminate in acute if exposure is continued.

The small amount of gas absorbed by the blood during subacute poisoning has no apparent action on the respiration. Apparently this is due to the rapid oxidation of hydrogen sulphide in the blood to form non-toxic products, small amounts being continuously detoxicated. If, however, the capacity to detoxicate, or in other words, the threshold for acute poisoning, is but slightly exceeded, a definite response, manifested in a hyperpnea, is almost immediately produced. With continued exposure the hyperpnea soon terminates in apnea vera. These symptoms are distinctly evident in a narrow range of concentrations above those causing subacute poisoning. Respiratory paralysis occurs in a few seconds in most cases of acute poisoning in industry. There is no indication that abnormal alteration of the hemoglobin takes place, nor that the poisoning is cumulative, nor of chronic poisoning other than would be expected from repeated irritation of the eyes and respiratory passages.

Absorption Through the Skin—The possibility of acute poisoning by absorption of hydrogen sulphide through the skin is a moot question. Some investigators¹⁴ have found that it is absorbed through the skin of guinea pigs, but in lethal amounts only when large areas are exposed to the pure gas. Others¹⁵ have noted only erythema of the exposed parts after 60 minutes' exposure to pure gas. With exposure of the naked arm of man to the pure gas for 60 minutes, dark coloration of the skin, spots similar to flea bites and red mottles, followed by erythema, were observed. No action on the nervous system was noted. In testing devices for respiratory protection, the U. S. Bureau of Mines frequently conducts experiments in which the entire surface of the body of men is exposed for 30 minutes to 2 per cent hydrogen sulphide in air. No symptoms of poisoning, discomfort, or discoloration of the skin have been observed.

Physiological Response—The physiological response attending exposure to various concentrations by volume in air is as follows:

0.005 to 0.010 per cent: Subacute poisoning—Slight symptoms such as mild conjunctivitis and respiratory tract irritation after 1 hour exposure.

0.02 to 0.03 per cent: Subacute poisoning—Marked conjunctivitis and respiratory tract irritation after 1 hour exposure.

0.05 to 0.07 per cent: Subacute poisoning—Dangerous in $\frac{1}{2}$ to 1 hour.

0.07 to 0.10 per cent: Possibly acute poisoning—Rapid unconsciousness, cessation of respiration, and death.

0.10 to 0.20 per cent: Acute poisoning—Rapid unconsciousness, cessation of respiration, and death in a few minutes.

These data are in substantial agreement with those previously cited.^{4, 5, 6, 7}

SYMPTOMS, SUBACUTE POISONING

Conjunctivitis (gas eyes)—Cases of conjunctivitis, known in the petroleum industry as "gas eyes," range from mild to severe; if severe, the conjunctiva is swollen and markedly inflamed. The secretions are increased and a mucopurulent exudate may develop. Sometimes there is a cloudy cornea, destruction of outer cell layer, and marked blurring of vision. The eyes may itch or smart, and pain is felt on exposure to light. It is common to see persons who have been exposed to hydrogen sulphide bearing gas (sour gas) sitting under some shade with their caps drawn over their eyes. Another common symptom is a feeling of roughness or dryness of the lids much like fine grains of sand or dirt in the eye.

Rhinitis, Pharyngitis, Laryngitis, and Bronchitis—Cases of irritation of the respiratory tract are somewhat less common than those of conjunctivitis. The symptoms range from a dryness in the nose and

throat, with a dry cough, to pain and the feeling of a foreign body in the throat. With more severe exposure this is accompanied by a sensation of tightness and rawness in the chest and later by mucopurulent expectoration, similar to a diffuse bronchial catarrh. With more severe exposure pulmonary edema may occur with scattered areas of hemorrhagic or purulent consolidation.

SYMPTOMS, ACUTE POISONING

With concentrations which but slightly exceed the threshold for acute poisoning, increased respiration over a short period followed by apnea vera may occur. The usual symptom of acute poisoning is unconsciousness within a few seconds, coming on without pain or significant warning. A choking sensation is sometimes experienced, but the period between this symptom and unconsciousness is so short that it rarely permits the victim to escape. As a rule, unconsciousness is followed immediately by cessation of respiration and frequently a short period of tonic convulsions. The heart continues to beat 5 to 10 minutes, during which rescue must be effected and artificial respiration given, otherwise cardiac failure and death will follow. Death is due primarily to asphyxiation.

ODOR INTENSITY AND SENSE PERCEPTION

In low concentrations hydrogen sulphide has a characteristic disagreeable odor which is nauseating to some people. Accordingly, it has been termed "stink damp." The intensity of odor cannot be used for judging the amount of gas present, because exposure for a minute or two to very low concentrations, or a shorter to higher, causes an apparent fatigue of the sense of smell, with disappearance of both the degree and character of the odor. This effect is more and more pronounced with increasing concentrations, until it is no longer perceptible. Instead, an acid-like effect or a slight sensation of choking and suffocating is noticeable. A metallic taste is often noted, especially if the person has metal fillings in his teeth.

Measurements of the odor intensity have been made under strictly controlled conditions. Observers who had previously been in hydrogen sulphide free air recorded the impression of the first sniff, thereby reducing fatigue to a minimum. The odor intensities obtained for various concentrations are as shown in Table I.¹⁰

These data show that in the absence of the factor of fatigue, the odor should be strong, cogent, and forceful in a concentration of 0.0027 per cent, or half the previously designated concentration for 60 minutes' exposure without serious subacute poisoning. In most cases, however, the worker's sense of smell becomes fatigued so rapidly that the actual sense impression is an odor of faint intensity or less, so

TABLE I
ODOR INTENSITIES FOR VARIOUS CONCENTRATIONS OF H₂S

Intensity of odor	Concentration of H ₂ S in air	
	Parts per million	Per cent by volume
No odor	0.022	0.0000022
Detectable; minimum perceptible odor	0.13	0.000013
Faint; a weak odor, readily perceptible	0.77	0.000077
Easily noticeable; moderate intensity	4.6	0.00046
Strong; cogent, forceful, not intolerable	27.0	0.0027

he often continues his exposure without apparent discomfort until sub-acute poisoning has ensued.

These measurements also explain the reason for lack of definite trouble from the quantities of hydrogen sulphide in chemical laboratories. The odor is detectable to a person entering the laboratory from fresh air in about 1/400 the maximum concentration for prolonged exposure without serious effects.

TREATMENT FOR POISONING

Sub-Acute Poisoning—The treatment of sub-acute hydrogen sulphide poisoning varies with the part affected, the degree of poisoning, and the existence of secondary complications. This necessarily makes the treatment symptomatic and leaves the physician to his choice of procedure for the particular condition. In view of the complications which may arise the treatment of sub-acute poisoning, even the mildest form, should always be carefully performed by a competent physician.

Acute Poisoning—In acute poisoning unconsciousness and cessation of respiration usually occur in a few seconds to a minute after exposure, followed in 5 to 10 minutes by cardiac failure and death, primarily due to asphyxia. In order to save life, rescue must be effected and artificial respiration applied within a few minutes after the accident occurs. Also, the rescue and treatment must be effected by fellow workmen because time does not permit summoning aid or transporting the victim to a hospital.

The major steps in the treatment of acute poisoning are: (1) get the patient into fresh air; and (2) give artificial respiration immediately if breathing has ceased, become markedly labored or impaired. The Schaefer method is simple and efficient.¹⁷

Experience has repeatedly shown that if rescue is effected and artificial respiration applied within a few minutes after the victim is overcome, life can be saved almost invariably. On the other hand, experience has also shown that a delay of 10 or 15 minutes jeopardizes the chances of recovery, though this should not be taken as an excuse for laxity in carrying out the prescribed treatment.

The importance of self-protection of those effecting rescue should be emphasized. Cases are on record where the first, second, and even the third person going to the rescue of a fellow workman have all suffered the same fate. The rescuer should always calmly, but expeditiously, plan the procedure, using all available means for self-protection. He should remember that he can hold his breath and remain conscious and unharmed much longer than the time required for the gas to render him unconscious if he breathes an atmosphere that contains enough hydrogen sulphide to cause acute poisoning. He should never enter a confined place, such as a tank, a derrick cellar, or a sewer, unless he uses at least a life line held by two attendants in fresh air, who are capable of giving artificial respiration, because it is very likely that he will be rendered unconscious. If suitable respiratory protective equipment is available it should be used in conjunction with the life line.

PREVENTION AND RESPIRATORY PROTECTION

Protection from hydrogen sulphide poisoning may be effected by (1) instruction; (2) mechanical devices for confinement or removal of the gas from places frequented by workmen; and (3) respiratory protective devices.

Instruction—Persons working in industries or at places where there is a potential exposure to hydrogen sulphide should be instructed regarding the properties and dangers of the gas; ways of avoiding exposure; all should be trained in giving artificial respiration,¹⁷ the treatment for acute poisoning. It is believed that most cases could be averted by care on the part of workmen to avoid exposure. The value of training in artificial respiration is borne out by the many lives that have been saved by that means.

Mechanical Devices—The hazards can be mitigated to a large extent by mechanical devices which will exclude or convey the gas from places frequented by workmen, such as the use of ejectors which take the gas from the casing at a place below the derrick floor; gas-tight look-boxes in refinery receiving houses; and the use of closed systems whenever possible.^{5, 8, 9}

Eye and Respiratory Protection—Devices which will give satisfactory eye and respiratory protection are available.^{5, 18} The respiratory protective devices may be divided into three general classes:

Canister gas masks—A canister-type gas mask consists of a face-piece attached to a canister filled with a gas absorbent. Granular soda-lime is generally used for acid gases as a class, of which hydrogen sulphide is a member. For the petroleum and other industries in which organic vapors, as hydrocarbons, occur and against which protection is also desired, the canister is filled with a mixture of granular soda-lime and granular charcoal. The latter is used to absorb organic vapors as a

class, but is also effective for hydrogen sulphide, thereby giving additional capacity to the canister. Devices which will give protection against 2 per cent hydrogen sulphide are available.

Canister gas masks merely remove the deleterious gases. They do not enrich the air or supply oxygen. Accordingly, they cannot be used in atmospheres which do not contain enough oxygen to support life. Their use is thus limited to places where an oxygen content above 17 per cent is assured.*

Hose masks—A hose mask is essentially a gas mask face piece connected to a length of hose through which fresh air is supplied, either by the breathing or by a hand operated blower at the fresh air intake. Hose masks are especially useful for entering tanks or similar confined spaces where the distance from fresh air does not exceed 100 to 150 feet. As the wearer is supplied with fresh air, hose masks will protect against any irrespirable atmosphere that the wearer's skin will bear.

Self-contained breathing apparatus—The self-contained oxygen breathing apparatus¹⁹ is a device which supplies oxygen from a small cylinder of the compressed gas. The period of use without recharging ranges from ½ hour to 2 hours of hard work, according to type of apparatus. The atmosphere breathed is entirely independent of external conditions. With some types there is, however, a possibility of permeation of the rubber breathing bag by gasoline vapor when used for extended periods. The self-contained breathing apparatus allows greater freedom of movement and range of operation than the hose mask. It is recommended, however, that a life line be used in all cases where men enter tanks containing a high concentration of hydrogen sulphide or petroleum vapor. As self contained oxygen breathing apparatus are equipped with mouthpieces and not face pieces, gas-tight goggles must be used in conjunction with the apparatus.

Goggles—Discomfort and incapacitation from eye irritation is by far the most prevalent trouble from hydrogen sulphide. The eyes appear to be more susceptible to irritation and to cause greater discomfort and pain than the respiratory passages. In many operations such as drilling in gas, pulling tools, casing or closing-in wells, where there is repeated exposure of a few seconds to flows of gas, the workmen hold their breath but keep their eyes open. Gas-tight goggles will give protection in these cases.

SUMMARY

1. Hydrogen sulphide occurs more widely, is more toxic, and constitutes a greater industrial health hazard than is generally realized. The principal health hazardous occurrences of the gas are in connection with gypsum mines, sulphur mines, tunnels and caissons in certain localities, sewers and other confined spaces where decomposition of organic matter takes place, blasting of heavy sulphide ores, use of black blasting powder in coal mines, natural gas from certain fields, production and refining of high-sulphur petroleum, its use as a reagent in manufacture of dyes, pigments, and chemicals, and in the rayon industry. The toxicity is comparable to hydrogen cyanide.

2. Two distinct types of poisoning exist—subacute and acute. The former is due to a direct irritating action of the gas on the tissues producing conjunctivitis and moderate to severe respiratory irritation. Acute poisoning is the result of a toxic action on the nervous system produced by the absorption and presence of hydrogen sulphide in the blood. Unconsciousness and respiratory failure usually occur within a few seconds after exposure and the important reaction is paralysis of respiration followed in 5 to 10 minutes by cardiac failure. There are no warn-

* As low as 12 per cent oxygen will sustain life, but to include a factor of safety, 17 per cent is advised.

ing symptoms and no pain. Death from acute poisoning is due primarily to asphyxia.

3. There is no indication that abnormal combinations with the hemoglobin are formed or that the poisoning is cumulative. Also, there is no indication of a chronic type of poisoning other than would be expected from repeated irritation of the eyes and respiratory passages. The gas is rapidly oxidized in the blood to form non-toxic compounds, ultimately sulphates.

4. Treatment of the subacute type of poisoning is principally symptomatic. With acute poisoning, rescue must be effected and respiration induced at once by artificial means.

5. Although the characteristic odor of hydrogen sulphide can be detected in dilution of 1 part in 10 million parts of air (a concentration far below that causing deleterious effects after prolonged exposure), fatigue of the sense of smell occurs rapidly, thereby excluding the use of the odor intensity as a warning.

6. Hydrogen sulphide in 100 per cent concentrations has been found to have a surface action on the skin (discoloration, red mottling, and erythema). An exposure of the naked arm for an hour, however, did not cause symptoms of action on the nervous system. The entire body of persons has been exposed 30 minutes to 2 per cent hydrogen sulphide in air by volume without noticeable effects of any kind. It is concluded that no serious trouble will be experienced by absorption through the skin when respiratory protective devices are worn.

7. Suitable types of respiratory protective devices in the forms of canister gas masks, hose masks, and self-contained oxygen breathing apparatus are available. Each type of device has its field of use and its limitations.

8. The training of workmen to avoid exposure; the design of equipment to eliminate places of exposure; the use of respiratory protective devices for performing operations in contaminated atmospheres and for emergency work; and the training of workmen in methods of emergency treatment will markedly lessen industrial hazards from hydrogen sulphide.

Are the Indians Dying Out?*

FREDERICK L. HOFFMAN, LL D., F. A. P. H. A.

Consulting Statistician, Prudential Insurance Company, Newark, N. J.

THIS important question of vital concern to our strictly native population was first raised in an essay entitled "Preliminary Observations Relating to Indian Civilization and Education," published by the Bureau of Education as a contribution to the Philadelphia Exposition of 1876. The author of the report was S. N. Clark, who gave an interesting account of Indian population statistics, estimating for the year 1876 a total Indian population of 291,882. The estimate of the Indian Office in the census of 1870 was 313,371.

While the report in question contains much valuable information, it fails to deal with the fundamental question of defining an Indian for census purposes. Obviously to ignore the large amount of race intermixture which has taken place since the settlement of the country, and which constantly tends to merge persons of Indian blood or part Indian descent into the white race, fails to take cognizance of a situation which at all times has complicated efforts to determine the question whether the true Indian is dying out. The true Indian in this sense is the full blood without white intermixture, or at least an Indian of one-fourth degree of intermixture, in which Indian physical traits are still fairly cognizable. It would be utterly hopeless to estimate the number of persons enumerated as whites who have Indian blood in their veins, but it must have reached prodigious proportions during the long course of years. It may even be questioned whether it is fair to enumerate as Indians persons who have one-fourth Indian blood and three-fourths white blood. Probably a better compromise would be to enumerate as Indians only persons who are of not less than one-half Indian origin.

Since 1910, the U. S. Bureau of the Census has made no serious attempt to enumerate the Indian population according to degree of racial intermixture. In that year the Indian population of continental United States, exclusive of Alaska, was 265,683. Of this number, 56.5 per cent were full bloods, 35.2 per cent were mixed bloods, while for 8.4 per cent the degree of intermixture was not stated. The mixed

* Read before the Vital Statistics Section of the American Public Health Association, at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

blood Indian population numbered 93,423, of which 8,000 were white and Indian intermixture; 2,555 negro and Indian; 1,793, white, negro and Indian; 80 other intermixtures, while for 1,265 the origin of intermixture was unknown. The percentages of intermixture vary, of course, widely for different tribes. Some are practically pure blood, like the Navajos of Arizona and New Mexico, while others have practically lost all Indian characteristics. For all practical purposes the question as to whether the Indians are dying out is therefore one which concerns chiefly the pure bloods, or the type which is still maintaining typical Indian characteristics. It is to be hoped that the forthcoming census will concentrate attention upon two points, namely, whether the Indian enumerated is of pure blood or mixed blood origin. Without anticipating the results of the 1930 census, I feel reasonably safe in stating that the probable number of pure bloods will not vary materially from that in 1910. Unfortunately no such differentiation was made in the census of 1920.

The present discussion is not concerned with tribal mixtures although that question is one of no small degree of practical importance. Of the 150,053 full blood Indians enumerated in 1910, 139,389, or 92.8 per cent, were full tribal bloods, while 10,251 or 6.8 per cent were of mixed tribal origin, and for 513 persons the tribal blood of one parent was unknown.

Aside from the complications arising from a complete and accurate enumeration of Indians on the ground of racial purity, there are still more serious difficulties in tracing the entire Indian population of the country in view of the half-hearted attempts which have been made in this direction by the census in former years. It is characteristic of all the estimates of Indian population that they rest, to a large extent, upon mere conjecture, and hence all speculations as to whether the Indians are dying out are too largely conjectural to be entitled to entire confidence.

The first serious attempt to enumerate the Indian population was made by the Rev. Jedidiah Morse, whose Report to the Secretary of War was published in 1822. In this enumeration there were numerous omissions, due to the unsettled condition of the country, which seriously invalidated the totals. The figure given was 471,034. Estimating inevitable omissions, partly affected by boundary limitations, it is probably safe to assume that the Indian population in 1820—at that time largely full bloods—was 500,000.

In 1850 a second serious attempt was made by H. R. Schoolcraft, one of the outstanding authorities on Indian Affairs. He arrived at an estimate of 388,209. The census of 1850 placed the Indian popula-

tion at 470,764. Mr. Schoolcraft's figures would indicate that during the 30-year interval the Indian population had decreased over 100,000. He made a second report in 1857 in which he estimated the Indian population to be 379,264. In 1870, the U. S. Bureau of the Census made a further effort to enumerate the Indians and the number arrived at was 313,712. Thus during the 20 years intervening from 1850 to 1870, there was a further decline as ascertained by the methods of enumeration then in vogue.

It would carry me entirely too far to discuss the fallacies inherent in practically every estimate thus far presented. The most impressive recent discussion on the question is an essay on "The Aboriginal Population of America North of Mexico," by James Mooney, another outstanding authority on Indian affairs, published in the Smithsonian Miscellaneous Collections of February 6, 1928. This report includes a wealth of data not heretofore available, particularly with reference to extinct tribes, of which he enumerates quite an impressive array, suggestive of the conclusion that small tribes are much more likely to become extinct than larger ones which are more resistant to the encroachments of the white population. Mr. Mooney estimates the Indian population of the continental United States at 266,000, but adding thereto the Indians of British North America, Alaska and Greenland, he arrives at a total of 406,000 for North America. While Mr. Mooney gives the Indian population of Canada as 101,000, the Canadian census of 1921 gives it as 110,596. This raises another question of accuracy, namely, how far the Indian tribes migrate from the United States to Canada, particularly along the border of New York State and British Columbia. Without enlarging upon Mr. Mooney's interesting and instructive investigation, I take it that the general conclusion would be to the effect that the Indians are declining in population and that the ultimate extinction of many of the smaller tribes at least is a foregone conclusion.

Mr. Mooney estimated the original Indian population of New England as about 25,000, practically all of whom have disappeared. In New York State the Indian population is between 5,000 and 6,000, but this number includes so large a number of mixed bloods that probably few full bloods remain, while the population itself has reached a stationary condition. Of the once prominent Montauk tribe on Long Island, said to have numbered 6,016, only 30 remained in 1907. These melancholy results have been observed in practically all parts of the country with the possible exception of the Southwest.

The Navajo population problem I have discussed elsewhere, pointing out that that tribe, as much as any in the country, is very well

holding its own and now probably numbering as many as at any time during its historic period. A complete enumeration of the Navajos made by the Bureau of Indian Affairs under the direction of Rachel M. Jenss during the summer of 1928 showed over 40,000, practically all full bloods, compared or contrasted with about 10,000 enumerated by various methods in 1857. It is to be hoped that the Indian Office will continue this method of enumeration, which includes finger printing and numerical disc distribution, for at least the principal outstanding tribes, particularly the Chippewas, the Sioux, and the Indians of California and Oklahoma. In Texas, where the Indians, even 30 years ago, were quite numerous, the number remaining in 1910 was only 702. Recent investigations, however, suggest that the number is somewhat larger, in that some Indians are located in remote sections of the state, eking out a precarious existence, calling for Congressional aid in the purchase of lands.

The only other notable attempt to estimate the past Indian population of the country was made by Prof. H. J. Spinden, Peabody Museum, Harvard University, published in the *American Geographical Review* of October, 1928. Prof. Spinden arrived at the conclusion that there are fewer Indians today than at the coming of the Europeans, which is, of course, accepted by all who are familiar with the facts. He estimated that about 1200 A.D. the number of the red race in the entire Western Hemisphere was between two and three times that at present, or say between 50,000,000 and 75,000,000; also that the present equivalent of Indian blood in the Western World is in excess of 25,000,000 individuals; but he does not give separate estimates for the United States. He accepts, however, the Indian Office returns for 1921 which give an estimated Indian population of 349,964.

Prof. Spinden is of the opinion that the main factor accounting for the diminution in population has been disease in epidemic form. It is that conclusion which suggests the importance of the Indian population problem to the American Public Health Association—in former years practically completely ignored as an outstanding problem in our American public health administration. In season and out for a number of years the late Dr. Joseph K. Dixon called attention to the Indian population problem, picturesquely referred to as "The Vanishing Race." If Dr. Dixon's ideas could have been carried out through the aid of some great foundation much might have been done to place the facts of our Indian population upon a sound statistical basis. Frequent statements as to the lamentable health conditions of Indian reservations or settlements otherwise are no longer in strict accordance with the facts. It is my own conclusion based on many years of ob-

servation that health conditions during the last three decades have been very materially improved, and were never better than at the present; however much remains to be done to make them conform to the sanitary ideals of the white population.

Every question of race survival involves the accurate ascertainment of the birth rate and the death rate and the excess of the former over the latter. What this excess is in the Indian population is not at the present time accurately ascertainable. Fortunately the Bureau of Indian Affairs during 1928 established a Division of Vital and Medical Statistics which is making strenuous efforts to improve both birth and death registration. The statistics collected heretofore by the U. S. Bureau of the Census for the Indian population left much to be desired. As regards births particularly, there are great difficulties to be overcome, the solution of which will require years of persistent effort and adequate field and follow-up organization.

The efforts of the U. S. Bureau of the Census in extending the registration area of the country at large are precisely those which would be most useful in extending birth and death registration among our Indians, but at the outset it is most important that the mere facts of births and deaths should be ascertained before efforts are made to improve the information contained on the birth and death certificates with reference to causes or connecting circumstances. With the improvement of the Indian medical organization, rapid progress in this direction may be anticipated. Indians are learning to make more general use of the hospitals provided for their needs, even for maternity cases, which, of course, is most desirable, and in course of time will lead to better data on births and deaths.

SUMMARY

1. The question as to whether the Indians are dying out cannot be answered in a satisfactory manner at present. It is sincerely to be hoped, however, that the census of 1930 will give particular attention to the accurate and complete enumeration of the Indian population according to degree of blood intermixture so that the full blood Indian population may be ascertained, at least with approximate accuracy. It is gratifying in this connection to be able to say that there is full co-operation between the U. S. Bureau of the Census and the Bureau of Indian Affairs, giving encouraging assurances in this direction.

2. All speculations regarding the survival of Indian tribes should rest solely upon the full blood population, for the remainder of mixed bloods represents a heterogenous mass of people imperceptibly shading off to the white population, who cannot be accurately enumerated by any method known to science. It has been suggested that blood tests would be successful but such would obviously be inapplicable to a census enumeration.

3. The question of race survival is obviously, in the case of the Indians, pri-

marily a question of an excessive death rate. The Bureau of Indian Affairs therefore should be encouraged in every way possible to continue in its present efforts, while nothing should be left undone to secure for it an adequate Congressional appropriation.

4. The outstanding mortality problem of the Indians is tuberculosis and non-tuberculous respiratory diseases. The reduction of these depends essentially, on the one hand on better earning power and better nutrition, and on the other on better medical and hospital service. What has been done in this direction is suggestive of a large measure of progress indicative of further advances in the near future.

5. The outstanding need of the Indian health situation is for more trained and otherwise competent hospital and field nurses. These can aid materially in prenatal and postnatal work, directed toward the reduction of the excessive mortality in infancy. Coöperation has been given the Bureau of Indian Affairs in this direction by voluntary health promoting agencies.

6. Finally it may be said that the Indian is a most deserving type of our civilization, and entitled to every possible consideration that will aid in his survival. The race has always produced men of outstanding ability, showing will power, courage and intelligence, and its leaders may be trusted to aid every deserving effort demanding the fullest coöperation on the part of the Indian people. But unless present-day efforts for the amelioration of living conditions and the lowering of the death rate are maintained at the highest possible level, the dramatic picture of a vanishing race will unquestionably come to a reality, much to our sorrow and much to our shame.

Size of the Family and Mental Ability of Children—Germany

IN an effort to ascertain the relation between the size of the family and the quality of the child's school work, as a partial reply to the question as to the rate of propagation of the less intelligent of the population, a study was made at the suggestion of the well known biologist Prof. Lenz, of Munich, of 870 public school children.

The group consisted of (1) normal children, (2) retarded children unable to follow the regular course, but able to complete a part of the required course, and (3) mental defectives.

It was found that families of the children below normal mentality were $1\frac{2}{3}$ times as large as those of normal children, also that the latter families did not reproduce themselves sufficiently to maintain the stock, while those below normal showed a definite increase. These results are similar to those obtained previously by another writer in another city.

The normal children in this study were divided into five groups according to their school marks. Those in the two highest groups came from families with a birth rate below the average for that city; in the two lowest groups the birth rate was above the average; moreover, the families of the children with the lowest marks had a birth rate twice as high as those with the highest marks. The above data also agree on the whole with those obtained by two other writers for schools of another city.—*Archiv. für Rassen- und Gesellschaftsbiologie*, Munich, 22, 2: 191, 1929.

Thermal Death Points of Pathogenic Bacteria in Cream and Ice Cream*

CAROLYN OLDENBUSCH, MARTIN FROBISHER, JR., AND
J. H. SHRADER, PH. D., M. D., F. A. P. H. A.

Research Laboratories of the Department of Health, New York, N. Y.

CONSIDERABLE study has been made of the thermal death points of bacteria in milk. Little has been done to determine whether the pasteurization temperature and time (143.5° F. for 30 minutes)¹ recommended is sufficient to kill the non-spore bearing pathogenic bacteria which may contaminate cream or ice cream. The question arose as to whether the higher percentage of butter fat in cream or ice cream would act to protect the bacteria in ordinary pasteurization.

The methods used by Park² formed the basis for the test procedures. The organisms used were:

1. Two strains of *B. typhosus* recently isolated from cases
2. Two strains of beta type hemolytic streptococci, one from scarlet fever, the other from septic sore throat
3. A culture of tubercle bacillus of the bovine type

The typhoid bacilli and the streptococci were grown in veal broth for 18 hours, then diluted with sterile broth to an appropriate density. The tubercle bacilli were cultivated on glycerine beef broth. The pellicle, after 3 weeks' growth, was filtered off, weighed and emulsified in sterile physiological saline, and diluted to a final concentration of 0.2 mg. of dry tubercle bacilli per c.c. of suspension.

Cream with 50 per cent butter fat content was sterilized in the autoclave for 30 minutes at 15 lb. pressure. For the test, 9.9 c.c. were measured into each of a series of small bottles. After heating until the cream was at the test temperature, 0.1 c.c. of the culture was added to each bottle. These were then stoppered tightly, vigorously shaken, and submerged in the water bath at the test temperature. Five temperatures from 135° to 145° F. were used. Samples were taken at various intervals. After heating for the desired time, the bottles were removed from the bath, shaken, and covered with cracked ice. After chilling, the cream was tested as follows:

* Read at a Joint Session of the Public Health Engineering and Food, Drugs and Nutrition Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

1. For the isolation of *B. typhosus*, six brilliant green agar plates were used. Two were inoculated with 0.2 c.c. each and one with 0.1 c.c. of the cream, this inoculum being streaked over the other three plates. At the same time, two tubes of bile peptone solution were inoculated with 2 c.c. of the cream. These were incubated for 18 hours for enrichment, and the bile was then plated on brilliant green agar. All plates were examined after 18 hours' incubation and slide agglutinations done with all suspicious colonies. As a further check on positive findings, the suspicious colonies were fished to Krumwiede's triple sugar medium.

2. For isolation of the streptococci, 1 c.c. and 0.1 c.c. amounts were pipetted into tubes of melted blood agar, which, after mixing, were poured into Petri dishes. One c.c. of each sample was also inoculated into tubes of blood broth for enrichment, and after 24 hours' incubation, plated with blood agar. All hemolytic colonies appearing on these two series of plates were fished into blood broth and incubated. As a final check, blood plates were poured from all fishings to determine that the streptococci recovered were of the beta hemolytic type.

3. Guinea pigs were used to test the survival of tubercle bacilli, three pigs for each sample. Each pig was inoculated subcutaneously into the knee-fold region with 1 c.c. of the cream. Pigs dying within 8 days were discarded; those dying at a later date were autopsied; those surviving 42 days were killed and autopsied. Smears were made of all suspicious lesions and examined for acid-fast bacilli. When no acid-fast bacilli were found, subinoculations were made into other guinea pigs.

The results obtained in the above series of tests are given in Table I. The streptococci did not survive heating in cream at 135° F. for 5 minutes, nor at 140° to 142° F. for 1 minute. At 143.5° and 145°

	145.0				*—	—	—	—	—	—

* Shortest time tried.

† No 1 minute specimen tried.

Unheated controls—original numbers of organisms per c.c.: *B. typhosus*, 87,000; Streptococci, 90,000; *B. tuberculosis*, 6 pigs inoculated developed generalized tuberculosis.

Average life of control pigs was 33 days. None survived full test time of 42 days.

+ indicates the organisms survived.

— indicates the organisms did not survive.

F., no test was made after 1 minute, but after 2 minutes there was no survival of streptococci. Typhoid bacilli heated at 135° F. were killed in less than 10 minutes, at 140° in less than 5 minutes and at 142° to 145° F. in less than 3 minutes. Tubercle bacilli in cream were killed* in less than 20 minutes when heated at 135°, in less than 10 minutes at 140°, in less than 7 minutes at 142° to 143.5°, and in less than 3 minutes at 145° F. In every case, controls of unheated infected cream contained a much larger number of pathogenic bacteria than cream would contain under natural conditions of contamination.

Similar experiments were done using an ice cream mixture supplied by one of the local ice cream manufacturers. This consisted of cream, milk, condensed milk and sugar in the proportions used commercially. The resistance of *B. typhosus*, streptococci, tubercle bacilli and a strain of *B. diphtheriae* was tested.

The technic for the determination of the survival of the *B. typhosus*, streptococci, and tubercle bacilli, was the same as in the preceding experiment. For the isolation of *B. diphtheriae* 1 c.c. and 0.1 c.c. amounts of the samples were pipetted into tubes of melted serum agar.

THERMAL RESISTANCE OF BACTERIA IN ICE CREAM MIXTURE

Organism	Temperature	Survival of Organisms after:				
	Fahrenheit	½ min.	1 min.	3 min.	5 min.	6 min.
<i>B. typhosus</i>	145	+	+	+	—	—
	150	+	+	+	—	—
Streptococci	145	+	+	+	—	—
	150	+	+	+	—	—
<i>B. diphtheriae</i>	145	—	—	—	—	—
	150	—	—	—	—	—
<i>B. tuberculosis</i>	145†	+	+	+	+	—
	150†	+	+	—	—	—
Numbers of organisms in unheated controls:						
<i>B. typhosus</i>	87,000 per c.c.				
Streptococci	46,000 per c.c.				
<i>B. diphtheriae</i>	2,000 per c.c.				
<i>B. tuberculosis</i>	6 pigs inoculated all developed generalized tuberculosis *				

* One of the control pigs survived 42 days. Average life of others was 34 days.

† All pigs showing generalized tuberculosis survived 42 days.

+ indicates organisms survived.

— indicates organisms did not survive.

After mixing, the agar was poured into Petri dishes. One c.c. of each sample was also measured into each tube of serum broth for enrichment. After 18 hours' incubation both plates and tubes were examined for the presence of *B. diphtheriae*.

The results of these tests are shown in Table II.

B. diphtheriae in an ice cream mix did not survive heating for ½

* Failure to produce infection in guinea pigs is considered as meaning bacilli were killed. These figures are somewhat lower than frequently given.

minute at 145° to 150° F. *B. typhosus* and the streptococci were killed in less than 5 minutes at these temperatures. Tubercle bacilli were killed within 6 minutes at 145° F., and within 3 minutes at 150° F. In comparing these results with those of the cream experiments, a slightly greater resistance was noted in the mix. This, however, was so slight that it falls within the limit of technical variation.

CONCLUSION

The time and temperature (30 minutes at 143.5° F.) recommended by the Committee on Dairy Products and Eggs, American Public Health Association, for the pasteurization of milk allows an ample margin of safety for the pasteurization of cream and of commercial ice cream mix.

NOTE: Part of the expense of this investigation was borne by the Research Laboratories of the National Dairy Products Corporation, Inc.

ACKNOWLEDGMENT: The authors desire to express their appreciation of the kind assistance of Dr. Park and members of his staff in these experiments.

National Children's Bureau of Argentina

A BILL for the establishment of a National Children's Bureau (Dirección nacional de la niñez) was recently introduced into the Congress of Argentina.

The main functions of the bureau will be to study the problems of improving the race of the future, to organize local councils in the capitals of the provinces and territories, and to establish institutions necessary for the carrying out of the work. The local councils are to open dispensaries for the treatment of physical and mental disorders of children. The bureau is to cooperate with the juvenile courts on the principle that a delinquent child is a sick child and must be treated as such, and is to establish reformatories with facilities for the medical treatment of the inmates.

The bill also provides for the establishment of a medical register of all school children in the country; this register to consist of individual records, each prepared after a thorough physical examination and mental test.—*Boletín del Museo Social Argentino*, Buenos Aires, Feb., 1930, p. 96.

Financing Home Sanitary Facilities on the Easy Payment Plan*

THIRTY states sent replies to the questionnaire submitted by the committee. Of this number only one, Maryland, limits the making of mechanic's liens to labor, and that only in Baltimore. From this it is assumed that the manufacturers of toilets, plumbing fixtures, and pipes have the same course open to them for installing these conveniences on a time payment basis as the roofing or paving contractors.

In answer to the second question as to whether any city or county had financed sanitary installations in the homes and then collected from the property owner at intervals, Maryland, Mississippi, North Carolina, South Carolina, Tennessee, and Wisconsin answered in the affirmative. With respect to Alabama, Mr. Hazlehurst says:

While a municipality has a right to bond for public improvements or to collect as taxes, if they so desire, the cost of such improvements, we have not found a town yet which has been willing to handle the work in this way. Legally and theoretically there is no reason why the work cannot be done in this way as sewers are installed. There seems to be, however, a mental attitude on the part of municipal councils which prohibits them from entering this field.

In Kansas, according to Mr. Boyce, the last legislature authorized service charges in cities of the third class, while health officers may order sanitary improvements to eliminate nuisances and charge the cost as a tax against the property. The statutes of Louisiana allow cities to force sewer connections, charge the cost against the property, and collect in five annual installments; but there is no record of any city having taken advantage of this provision. This is likewise true in Maine, Maryland, and Wisconsin. H. A. Kroeze of the Mississippi State Board of Health advises:

Several cities in the state have financed outright the installation of pit toilets and sewer connections and then collected on the installment plan over a period of 10 years. We have been able to interest several cities in this plan which has enabled us to do a vast amount of sanitation very easily, and over a short period.

Cities of North Carolina have availed themselves of the privilege of forcing sewer connections, and have collected, but usually have safeguarded the investment by tax liens.

* Report of the Committee on Rural Sanitation presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

A. E. Legare of the South Carolina Board of Health says:

Two towns have installed pit privies under contract for private parties, collecting monthly for 2 years to pay for such installations.

We are advised that in Tennessee:

Shelby County in the territory adjoining Memphis, 2 years ago put in thousands of concrete slab and concrete riser pit privies—some on a cash basis but a large part on credit.

Our next inquiry was whether any corporation or banking concerns were financing such installations, and on what basis. In Delaware we find the Delaware Mortgage Corporation at Wilmington finances such improvements and has a monthly charge for paying off the interest and principal. The Standard Sanitary Manufacturing Company has a division in its organization for handling such financing. In Maryland, Ohio, and Rhode Island, such improvements are handled through building and loan associations, while the Commercial Credit Company of Baltimore advises that it will make such loans in the ordinary course of business if applied for and the proper security given. In Mississippi the state laws allow cities to create a sanitary fund for the purpose of loaning money to property owners for the installation of sewer connections and plumbing fixtures. The cost of the installation is paid for by the city; property owners sign 10 notes bearing 6 per cent interest; and the money is repaid in 10 annual installments. When the city has a sufficient quantity of such notes, it reissues its own notes and sells these to financing corporations.

In North Dakota banks will loan money for such installations in the same manner as for other improvements, taking a mortgage on the property. With regard to this point, the State Sanitary Engineer of Rhode Island advises:

A number of plumbing firms and supply houses install sanitary facilities on the partial payment plan. . . . Two coöperative banks take first mortgages on property to cover any reasonable investment of this kind, payments to be spread over a term of years. We have also a considerable number of acceptance and finance corporations from whom small loans can be obtained to be paid back in weekly or monthly installments, usually at a rate of interest which is rather high. I am informed that some of the small contractors who take jobs on the installment plan simply endorse the notes for the work they have done and discount them with one of the acceptance corporations.

In Tennessee there are several financial institutions that handle paper on building improvements, particularly the General Securities Company of Nashville. Other institutions simply buy the lien notes after they have been made out. In West Virginia one insurance

agency constructs septic tanks and private sewer systems on a monthly payment basis.

In Texas some 15 communities ranging between 500 and 10,000 population have been able through the coördinated efforts of the local officials, the State Health Department, and finance corporations, to install numerous individual private plumbing systems and thousands of pit toilets, thereby bringing sanitary facilities to homes which otherwise would not have had this service—at least not for many years, or perhaps not at all. The State Health Department promoted the work and gave it moral support; the communities passed the necessary ordinances and acted as collecting agencies; while the corporations furnished the materials and made the installations upon the guarantee of the city for their pay.

In some of these towns, individuals were paying a scavenger fee of \$1.50 a month, but under the new system the surface and can toilets were replaced by pit toilets and a rental charge of \$1.00 a month substituted. Under the scheme employed by the Sanitary Appliance Company of Houston, the materials for the pit toilets were furnished and money advanced to pay for the labor of installing. The toilets were then leased to the householder, while the city became the collecting agency. The money accruing from these rentals or leases is used to pay the Sanitary Appliance Company first, including interest on its investment, and after that debt is discharged, the toilets become the property of the city, which continues to lease to the householder, the rentals accruing to the benefit of the city. By this method scavenger fees have been eliminated and eventually a sanitary fund is built up in the city's treasury, while the householder gets a better service at a lower cost.

The Crane Company advises that a partial payment method is now being tried out at its Utah branch. The Standard Sanitary Manufacturing Company advises that it is now offering a plan for financing plumbing in homes, provided the project is underwritten by a local plumbing firm. The Wolff Company has tried out the partial payment plan but it did not work satisfactorily.

It will be seen that the problem of financing home sanitary facilities on the deferred payment plan has been seriously attacked, although the solution has hardly gone beyond the experimental stage. It seems reasonable that a plan might be worked out which will meet the approval of health authorities, manufacturing and installing plumbers, contractors, and the householder.

On the basis of this study, the following conclusions are drawn:

1. Health authorities have found it profitable to encourage and give moral

support to commercial concerns which manufacture, sell, and install sanitary equipment, in extending their services to home owners on reasonable terms.

2. Where provision has not already been made, it might be profitable to encourage the passage of laws which will permit cities and counties to create a sanitary fund and issue warrants thereon for financing sanitary facilities such as water and sewer connections, heating appliances, screens, and suitable outdoor toilets; and allow the householder to pay in annual installments, say, over a period of 10 years.

3. Where it is not feasible for cities and counties to finance installations as indicated in "2," corporations should be encouraged to do so under a deferred payment plan which seems to be a legitimate and satisfactory outlet.

4. It has been shown that the cost of plumbing can be reduced if cities will adopt ordinances embodying the best features of the plumbing code devised by the Hoover Committee, and if manufacturing plumbers will employ modern mass production and distribution methods.

RECOMMENDATIONS

1. That this committee be resolved into a joint committee composed of representatives of the American Public Health Association and the Conference of State Sanitary Engineers; and that this joint committee invite representatives of the plumbing and heating industries, the U. S. Departments of Agriculture and of Commerce, and of the Federal Trade Commission, to assist in making further studies of the entire problem of financing home sanitary facilities.

2. That the work of this joint committee during the coming year be focussed upon a study of existing schemes of financing home sanitary facilities and to project plans which will facilitate their installation.

National School of Hygiene in Chile

A MINISTERIAL decree of December 11, 1929, provides for the establishment of a National School of Hygiene (*Escuela Nacional de Higiene*) for the purpose of training specialists in hygiene, bacteriology, and certain related subjects. Normal courses in personal hygiene and school hygiene will be given for teachers in primary, secondary, and normal schools. One of the departments of the school will be devoted to maternal and child hygiene.—*Diario Oficial*, Santiago de Chile, Dec. 28, 1929, p. 7080.

Epidemiology in State and City Health Organizations*

JOHN A. FERRELL, M. D., DR. P. H., F. A. P. H. A.

International Health Division, Rockefeller Foundation, New York, N. Y.

STATE and city health organizations, if properly constituted, will include as part of their basic structure provision for epidemiology. Certainly this is true in so far as this science is concerned with the study and control of the communicable diseases of man. Even the health organization of the town, county, or state, limited in personnel to health officer, nurse, inspector, and clerk, will find epidemiological activities essential. It should collect morbidity data, study cases of communicable diseases by clinical and laboratory methods, consider environmental factors, interpret the observations, and indicate and apply effective protective or control procedures with the utmost promptness and directness.

The organization having greater resources—which usually means that it serves an area having greater population and wealth, and as a rule greater interest—can introduce a considerable degree of specialization. That is, it can employ specialists or technical workers, such as epidemiologists, statisticians, sanitary engineers, and bacteriologists. Since the state health organization is expected to serve a vast area and to supply epidemiological and other specialized aid to the town and county organizations unable to have their own specialists, it should adopt the specialized type of organization, even when the total budget is relatively small. The local organization, on the other hand, is expected to supply immediate and continuous service throughout the community in home, school, and business establishments. These measures necessitate a large proportion of the expenditures for nurses and inspectors. The organization would not, therefore, be able to employ technical workers except when its budget was relatively large. It would usually be expected that a county or city having a health budget of from \$40,000 to \$50,000 yearly would employ technical workers in one or more branches of its service. When the budgets range from \$100,000 to \$1,000,000 or more for state or city organizations, we should expect to see well defined divisions for each of the

* Read at a Joint Session of the Health Officers and Epidemiology Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

essential specialized services. Each division would include at least one technical worker, frequently several, and the necessary clerical assistants.

Epidemiology, in most of the state and large city organizations, would constitute one of these divisions. In a number of the larger organizations there is not a separate division for the epidemiological service, but it is conducted as a subdivision of a major bureau for preventable or communicable diseases. Under this plan, the services for venereal diseases, tuberculosis, or malaria, may also form subdivisions. Certain states having approximately 500,000 inhabitants or less, and limited resources, have not yet been able to secure funds sufficient to finance all the basic branches of their health organizations. They have found it necessary to have one technical worker function as director of two divisions. For example, the laboratory director may have to serve also as epidemiologist, or *vice versa*. Such an arrangement is unfortunate and, of course, should be regarded as temporary.

Regardless of the exact scheme of organization, the importance of epidemiology should not be underestimated. Its director should have a status coequal with that of other division directors; the budget should be adequate; the salary attractive; and tenure assured on a merit basis. Moreover, the coöperation between the personnel of the epidemiology division and that of the other central divisions should be of the closest. If the division is to function effectively, it must assemble and classify all pertinent data regarding preventable diseases, interpret their meaning, and make its conclusions available for administrative guidance with the utmost promptness. The laboratory can supply primary information as to the presence of diseases; the vital statistician, mortality records; the sanitary engineer, information on danger or occurrence of diseases due to polluted water or milk.

Morbidity records are essential to any successful plan of disease control, but their value will be determined largely by their accuracy, completeness, the promptness with which they are received, and the information utilized. The epidemiologist is dependent upon the local health service to collect these records from the doctors and other sources. Moreover, the central or state health service has to depend to a very large degree upon the local organizations to carry out the best control procedures based upon present knowledge. Thus we are very largely dependent upon the local organization to collect epidemiological data and to apply the knowledge obtained to the control of disease. Existing knowledge and any new facts which may be discovered can be applied most satisfactorily when there has been established adequate local health machinery. Incidentally, it is extremely

unfortunate that the vast amount of knowledge now at our disposal is applied in such a limited way. All those who are familiar with the situation understand quite well that this is due to backwardness in the development of effective public health machinery, particularly for local or community service. The state epidemiologist, in the absence of local health organizations or without their hearty coöperation, will be able to accomplish comparatively little. These two branches, which are so basic in any sound scheme of public health organization, curiously enough have been relatively backward in their development.

Having considered the place which epidemiology should occupy, we might examine our health organizations to see how it has fared. Although the control of communicable diseases gave rise to the public interest which led originally to the establishment of health organizations, a number of related subjects during the past twenty years have commanded attention to a degree which has somewhat sidetracked the original purpose. In part this may be due to the greatly lessened importance of certain diseases, such as yellow fever, cholera, and plague, which in former times gave rise to disastrous epidemics. In part it may be due to the successive waves of interest stimulated in sanitary engineering, tuberculosis, hookworm disease, malaria, venereal diseases, maternity, infant welfare, and so on. These stimuli have been most fortunate, but with them there should have been a corresponding growth of interest in communicable disease control, including the epidemiological service which supplies the knowledge upon which the control efforts should be based.

Of the 48 state health organizations, about 20 rely upon the state health officer or a member of his staff without special training to function as epidemiologist. About 25 have budgets for one or more epidemiologists, most of whom are doing, or are capable of doing, creditable work. About 8 have appointees whose activities relate largely to quarantine and law enforcement and who do very little, if any, actual epidemiological work. Perhaps not more than 10 states have had the services of real epidemiologists for as long as 10 years. Ten or 12 others within the past 5 years have employed men who have taken courses in epidemiology in schools of public health.

Although I am less familiar with the status of epidemiology in the city health services than in the state, *Public Health Bulletin No. 164* states that in 1925 the 100 largest cities of the United States expended \$18,974,583 for specific health services and \$2,632,484 or 13.87 per cent was applied to communicable disease control. The states in 1925 (*Public Health Bulletin No. 184*) expended \$10,144,850, not including funds for tuberculosis sanatoriums. The percentage of their ex-

penditures that went into communicable disease control, exclusive of venereal diseases, ranged from 1.5 to 32.6. Although the figures are incomplete, it appears that only about 25 per cent of the states expended as much as 10 per cent of their resources on communicable disease control, exclusive of tuberculosis and venereal diseases, which were reported separately. The records do not indicate what part of the funds allocated specifically for branches of communicable diseases was applied to epidemiology either in states or cities.

The analysis for the state services shows that the salaries generally are too low to attract or hold the best type of men, and the compensation allowed in divisions of communicable diseases and epidemiology offers no exception to the rule. Only 3 states pay their directors as much as \$5,000 per year. Salaries in 10 others range from \$4,000 to \$4,800, and in 15 others from \$3,000 to \$4,000.

These figures lead naturally to a consideration of the kind of personnel that is engaged. In the state services, and the same is true I believe in the city services, a considerable number of very capable men are at work rendering fine service despite the poor compensation. One-third of the states perhaps have at least one man who, by training and experience, is qualified to conduct epidemiological field studies. In approximately half of the states the situation is far from satisfactory. It is not unusual for activities to be undertaken involving the expenditure of considerable sums by inadequately trained personnel. The activities are conducted in the absence of a health survey by qualified persons who could define the health problems, determine their relative importance, and outline the program of work calculated to yield the best return for each dollar spent.

Further evidence of the unsatisfactory situation is reflected in the absence—a few states and cities excepted—of complete and reliable morbidity records. Without accurate information as to the incidence of diseases, health departments can merely grope in the dark. Now that 17 states and 26 cities are each spending yearly from \$200,000 to \$5,000,000 (New York City \$5,000,000, Pennsylvania \$1,500,000), and other states, cities and counties relatively large amounts, need for more efficient guidance in public health measures is urgent.

As indicated, there has been improvement in the situation during the past 10 years; but progress seems to be too slow. A hopeful development was the conference, in Baltimore in 1927, of a group of more than fifty scientists interested in epidemiology. Their purpose was to obtain a consensus of opinion with regard to epidemiological services in public health organizations and to make it available for health agencies, legislative bodies and the public. The proceedings were published in the JOURNAL.¹ More extensive use, in my judg-

ment, should be made of them. As I was a member of a special committee appointed to draft recommendations for the "organization of epidemiological service within state departments of health" and as the conference in approving these recommendations voted that "the principles applying to state departments are also applicable to departments of large cities," I quote the recommendations as adopted:

1. There shall be a bureau or division dealing with epidemiology in each state health department coequal with other essential divisions in the organization.

2. The function of this bureau or division, with respect to investigation of disease, shall be:

(a) The analysis of morbidity statistics whether these be collected directly or through some other division.

(b) The correlation of the mortality statistics obtained through the division of vital statistics with the morbidity data.

(c) The securing of immediate information from the division of sanitary engineering or other divisions as to the prevalence of disease.

(d) The use of laboratory data as a source of primary information as to the existence of communicable diseases.

(e) To secure special service from any division as to the causative factors of disease.

(f) To classify, analyze, and interpret all available information with reference to disease, for administrative guidance in formulating sound plans of procedure, and acquainting health agencies, the medical profession, and the public with the facts.

(g) To conduct field investigations for the purpose of collecting or discovering facts essential to more effective control procedures.

(h) To assist local authorities in epidemiological activities.

3. The work of the division requires the services of professional, clerical, and field personnel.

(a) By "professional" personnel reference is made particularly to the director of the division. He should possess exceptional inherent qualities such as sound judgment, tact, and poise. He should be well grounded in the knowledge of medicine and public health, and have special training in the differential diagnosis of communicable diseases and a working knowledge of laboratory and statistical procedures. He should have enough assistants in the field to make the division activities effective.

(b) By "clerical" personnel we allude to secretaries and clerical assistants who can handle files, correspondence, and statistical data.

(c) By "field" personnel is meant those members of the staff of the division primarily engaged in procuring epidemiological data, and also the personnel of local health organizations, including the health officer, office assistants, public health nurses, and sanitary inspectors.

(d) The organization of the division of epidemiology should be of such character as to attract and hold competent personnel. There must be security of tenure, the compensation must be creditable, and there must be an opportunity for initiative.

REFERENCE

1. The Conference of Epidemiologists (at Johns' Hopkins University School of Hygiene and Public Health, May 12-13, 1927), *A. J. P. H.*, 17, 8: 777 (Aug.), 1927.

Improved Practical and Economical Methods of Mosquito Control *

MOSQUITO control, accepted as an important adjunct to the practice of public health engineering and preventive medicine, is steadily growing in scope and magnitude throughout the United States and the world. Whether the problem is one of disease transmission with illness and economic loss to employers and employees, or one of pestiferous proportions with its baneful effect upon human existence and a public health factor through irritation detrimental to comfort and health and reducing industrial efficiency, the demand for effective mosquito control is becoming more universal and is receiving increasing recognition.

Effectiveness is the keynote of successful control operations. Methods by which breeding places may be permanently eliminated—and this is the basic principle of mosquito control—depend, of course, upon local conditions and are thus removed from the application of any specific practice. Breeding places which cannot be disposed of are, however, susceptible to a more or less uniform method of treatment. For this purpose a great variety of oils and larvicides are employed, and frequently through lack of uniformity and suitability of material there is loss of effectiveness and money.

With the view of laying before the Public Health Engineering Section conclusive and constructive recommendations in the practice of control by oiling, your committee undertook the investigation of experiments with oils and oil mixtures to determine the question of suitable specifications.

Until a comparatively recent date practically no definite or conclusive data have been presented on the value of the various oils and oil mixtures and there has been a very limited understanding of their effect upon larval life. For such use there has been an inclination to accept almost any kind of oil available that would cover the surface of water, with the hope that a uniform film would remain long enough to accomplish suffocation—a result formerly held to be sufficient. Certain variations were attempted from time to time, here and there, without uniformity of purpose or results. Of late the question of the

* Report of the Committee on Mosquito Control, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

need for some toxic agent has demanded attention especially as concerns the control of pupae or securing a necessary rapid kill.

The following theories have been suggested by various investigators to explain the killing effects of oils on larvae.

1. Surface Tension—The physical properties of the oil layer reduce the surface tension so that the larvae are unable to hold themselves to the surface for the necessary breathing period, and drown.

2. Suffocation—The layer of oil acts as a barrier between the larvae and the air, causing suffocation.

3. Oil in Solution—A portion of the oil goes into solution and poisons the larvae.

4. Blocking of Tubes—The oil entering the siphon and tracheal tube, blocks them and impairs respiration.

5. Oils as Contact Poisons—The oil enters the siphon and tracheal tube and acts as a contact poison on tissue.

As a result of more recent investigations there was developed the more logical theory of "Oil Vapors Acting as a Toxic Agent," it being held that the vapor from inspired oils penetrates the tracheal tissue and produces lethal effect.

Outstanding in support of the last mentioned theory are the experiments carried out in New Jersey by Dr. Joseph M. Ginsburg for the State Agricultural Experiment Station which resulted in very definite conclusions recommended by your committee as a decided forward step toward uniformity in the practice of control by oiling. A complete report of these investigations has been published in the *Proceedings* of the Sixteenth Annual Meeting of the New Jersey Mosquito Extermination Association.

The following facts were established:

1. The toxicity of petroleum distillates is in direct proportion to rate of volatility and inversely proportional to the boiling point.

2. From the standpoint of mosquito control, the petroleum distillate oils can be divided into two groups:

Oils of low boiling points and high volatility, possessing high toxicity to larvae and pupae

Oils of high boiling points and low volatility, possessing little or no toxicity

3. Oils boiling from 200 to 550° F. kill larvae and pupae within 30 minutes by exerting a direct toxic effect.

4. Oils of high boiling ranges, such as lubricating and similar oils, act simply by suffocation, the rate of kill being in proportion to the thickness of the film and degree of surface tension.

5. Larvae, whose respiratory siphons are filled with non-toxic oil, do not develop into pupae.

6. Pupae whose trumpets and part of the thorax are filled with non-toxic oil can, under certain conditions, develop into adult mosquitoes.

7. The breathing tubes of larvae and the trumpets of pupae can readily penetrate the thin films of oil that are usually applied on mosquito breeding places.

8. For highly efficient mosquito control in the field the oil must not only form a uniform film but must also be directly toxic to larvae and pupae.

In carrying out the experiments the toxicity and penetration of a number of petroleum oil distillates, varying in boiling point from 200 to 700° F., and of different volatilities and viscosities, were tested on larvae and pupae. An interesting feature of the penetration test was the use of Sudan III which enabled the red stained oil to be traced wherever it penetrated the tracheas of the larvae and pupae.

The experiments also establish the important fact that although larvae containing a poorly toxic oil or non-toxic oil in their breathing siphons cannot develop into pupae, pupae in the same state can produce adults when the oil film breaks, which, to some extent at least, upsets the suffocation theory.

Even though suffocation by the use of non-toxic oils is possible, it would appear that because of the excessive amount of oil required and the great uncertainty of the film remaining intact long enough to accomplish a kill—which is never 100 per cent—for practical and efficient control operations that theory must be discarded in favor of oil vapor as a toxic agent; and the use of oil for any class of breeding restricted to those having a low boiling point and high volatility, making up in quick kill for limited lasting qualities.

If the question of more rigid economy is involved, a mixture of a sufficient amount of highly volatile oil having a boiling point range of say 300 to 500° F. and a high boiling point product such as the cheap waste crank case oil—the final mixture registering a Baumé gravity of 32 to 34°—will give good results as far as spreading and good stable film are concerned. If waste oil is used it is most important that it be very thoroughly strained. For that purpose a series of at least two screens, with the last one not larger than 40 meshes to the inch, is recommended.

The following interesting facts were developed tending to disprove, or indicate the comparative ineffectualness of, one or more of the old theories and supporting the theory of the lethal effect of toxic oils:

1. That volatility and rapidity of kill are inversely proportional to the boiling range, suggests that volatility plays an important rôle. It is also worthy of note that highly volatile oils are strong solvents of fatty tissue.

2. Larvae died before inspired toxic oil reached the sixth segment of the tracheal stems and frequently when but a minute quantity had entered the tip of the tube, showing that lethal effect was produced by the volatile gases penetrating into the tissues, an effect similar to that of ether vapors.

3. Larvae lived several hours after the tracheal stems were completely saturated with non-toxic oils.

4. Variations in the rate of kill of the different non-toxic oils applied under similar conditions.
5. Time required for kill frequently ran into many hours.
6. That a number of other theories have been offered would seem to show that the popular one of suffocation does not always obtain.

In the last analysis, however, oil in any form is not entirely satisfactory. There is need for a larvicide that will thoroughly mix in solution with any water in which mosquitoes may breed and effect rapid kill. To be economical and safe for domestic animals such an agent with its high cost and toxicity should be effective in at least 1 part to 10,000. Experiments along this line are now under way in New Jersey and it is the hope of the committee that similar investigations will be made in other states during the next year.

OTHER EXPERIMENTS OF INTEREST

Since the discovery in 1921 of the high toxicity of Paris green against *Anopheles* larvae, the use of that material has steadily increased in malarious regions. Although hand distribution still remains the standard method, several experiments in dusting by airplane to meet the need of more economical methods of application over large areas, have been carried out with a fair degree of success; but that method has not been developed to the point of being recommended for general practice. A further problem has been encountered in the varying degree of toxicity of the several brands of Paris green, which at present renders its use by any method uncertain. The suitability of the material as a larvicide is still maintained and efforts are being directed to the solution of the problems of quality and method of distribution.

In the development of new anti-mosquito agencies it is interesting to note that Robert Matheson and E. H. Hinman, Department of Entomology, Cornell University, recently discovered that the vermilion spotted newt, which occurs throughout the east and central states and Canada, possesses a stupendous appetite for mosquito larvae, a tendency of economic value in fresh water mosquito control if the breeding of this harmless salamander were made a part of the control program.

Recent experiments with *Chara fragilis* are also reported by Dr. Matheson with the statement that ponds in which *Chara* grows normally were found to be continuously free from mosquito larvae; that *Chara* transplanted to aquariums was shown to be lethal to at least four species of mosquito larvae—*C. pipiens*, *C. territans*, *A. vexans*, and *A. punctipennis*; and that a number of successful introductions

were made and found to have the same lethal effect when a vigorous growth was maintained. The results of these experiments are of especial interest in view of the doubt previously expressed in the recorded claim of the efficacy of Chara as a mosquito repellent. Certain other experiments in transplanting Chara which have come to the attention of the committee were unsuccessful because the necessary vigorous growth was not established in the new locations, an important consideration. The committee presents the subject with the suggestion of experiments on a wider scale.

In the matter of general practice in mosquito control your attention is invited to the fact that in an effort to correct the tendency of engineers to "build in" breeding places the Associated Executives of Mosquito Control in New Jersey have petitioned the engineering departments of the state, counties and municipalities, and all licensed engineers, to include in specifications for roadway and similar construction work a clause prohibiting the establishing of borrow pits and other depressions which may become breeding places, and also to provide for suitable drains for areas which would otherwise be locked in.

At the request of that association the State Board of Health has established the rule that all necessary measures must be taken to prevent the breeding of mosquitoes in any part of sewage disposal plants, a medium of mosquito production which has assumed alarming proportions.

The two last phases of practical mosquito control are recommended by the committee for general practice.

Social Service in Argentina and Uruguay

THE Museo Social Argentino, an organization for the study of social problems, with headquarters in Buenos Aires, has pointed out the need for modern social service in Argentina; it has recommended the establishment of a school for the training of social workers and has prepared and published a plan for such a school. A similar recommendation has been made in Uruguay.—*Servicio Social*, Santiago de Chile, 3, 4: 311, 1929.

Inter-Chamber Health Conservation Contest

WILLIAM BUTTERWORTH

President, Chamber of Commerce of the United States, Washington, D. C.

AUTHORITATIVE figures on public health show that one out of every four families in the country will have at least one serious illness in the course of a year, and that 2 per cent of our total population is at all times too ill for work. Rough calculations based on these figures, applied to the total annual income in the United States, indicate a direct monetary expense of something like \$2,000,000,000 a year for sickness. Distributing this amount evenly among the 27 million families of the country, it costs the average family the equivalent of \$80 a year through the loss of wages, salaries, cost of necessary medical care, and the like. In addition to this enormous loss, the total capital value of lives prematurely lost has been estimated as aggregating over \$6,000,000,000 annually.

Aside from the humanitarian aspects, these burdens weigh heavily on communities and individuals. There is encouragement in the fact, however, that medical and health authorities of the nation agree that something can be done about it.

1. Frank J. Osborne, Health Officer, East Orange, N. J. 2. John P. Kochler, M.D., Commissioner of Health, Milwaukee, Wis. 3. George C. Ruhland, M.D., Commissioner of Health, Syracuse, N. Y. 4. Edwin G. Ramsdell, M.D., Health Officer, White Plains, N. Y. 5. (Health Officer from Sidney, O., not present.)

Much of the tremendous economic losses resulting from injuries, sickness and death is preventable. Perhaps the major need today is to bring home to the public at large a knowledge of the benefits to be obtained through a promotion of public health education.

Recognizing health education work as a field of vital interest to organizations of business men, the Chamber of Commerce of the United States with the coöperation of the American Public Health Association, the National Association of Life Underwriters, and the U. S. Public Health Service, as early as 1926 began to work on a health conservation program. As a result of the success achieved in this field evidenced by the reports of active participation from many chambers of commerce, and encouraged by the accomplishments that have been made by insurance companies, industrial concerns and other organizations, our Seventeenth Annual Meeting last year adopted a resolution which declares:

In order to conserve life and health to the fullest extent there should be further development of national interest and of national activity. In efforts directed to this purpose the Chamber should participate and should enlist the widest possible coöperation on the part of its membership.

In carrying out this expression of our organization members, an Inter-Chamber Health Conservation Contest was launched in order to give the health activities of the member commercial organizations the stimulus of competition. The Contest, to be under the direction of the Chamber's Insurance Department Committee and Insurance Department, was announced on June 20, 1929.

From the very beginning of its health program the Chamber has realized that but little could be accomplished without the help of organizations interested in the technical aspects of such work. In the Health Contest the need of such assistance has been especially apparent and the enthusiastic coöperation and aid of the Committee on Administrative Practice of the American Public Health Association has been most valuable. Through the financial help of a number of member insurance companies of the National Chamber, the American Public Health Association, through its technical experts, has been enabled to render consultant service to nearly 100 of the contestants.

Local chambers, moreover, have been encouraged to seek the aid and coöperation of their local public officials and other public health agencies. *Without their help it was felt that advance in local health conservation achievements would be of but little moment.* On the other hand, the local health officials and agencies when backed by the wholehearted support of the business men of each community can increase the effectiveness of their efforts. Coöperation between local public health agencies and local business men has been the keynote of the Contest.

Planned generally to be from January 1 to December 31 inclusive, the period of the Health Contest during the initial competition of 1929 was made retroactive to January 1, though entry was allowed at any time during the year. The success of the Contest may be judged by the fact that, for 1929, more than 130 cities, representative of 38 states, the District of Columbia and the territory of Hawaii, participated. Of these cities 108, representing 30 per cent of the urban population of the United States, sent in records of their 1929 health conservation activities. Interest manifested in the Contest to date has been beyond all expectations. But from even a casual appraisal of the benefits to be gained, it is not surprising after all that so many communities should wish to take part in the movement.

In order that none of the participants in the Contest might be unduly handicapped, the various communities have only competed with those in comparable population classes. The population classes are as follows: Class I, over 500,000

population; Class II, 100,000 to 500,000 population; Class III, 50,000 to 100,000 population; Class IV, 20,000 to 50,000 population; Class V, under 20,000 population. Recorded activities of contestants in the various population classes have been most excellent, and it is felt that many with reports only slightly below the winners deserve recognition. In each population class, the first 5 cities following the winner have been given honorable mention and will receive engraved certificates.

It is a pleasure to give the names of these honor cities:

Class I—Detroit, Mich., Philadelphia, Pa., San Francisco, Calif., Brooklyn and Buffalo, N. Y.

Class II—New Haven, Conn., Rochester, N. Y., Cincinnati, O., Yonkers and Albany, N. Y.

Class III—Rockford, Ill., Pasadena, Calif., Racine, Wis., Harrisburg, Pa., and Greensboro, N. C.

Class IV—Cumberland, Md., Alhambra, Calif., Aurora, Ill., Durham, N. C., and Santa Ana, Calif.

Class V—La Salle, Ill., South Orange, N. J., Eureka, Kans., Palo Alto, Calif., and Natchitoches, La.

Certainly these cities are representative of the country as a whole and it is my sincere hope that the progress made in health conservation during the first year of the Contest will spur them to greater efforts and successes in the future.

It now becomes an added pleasure to present the awards to the winners in each of the population classes. (Mr. Butterworth then proceeded to present the award—a large bronze plaque—to each of the five winning cities: Milwaukee, Wis.; Syracuse, N. Y.; East Orange, N. J.; White Plains, N. Y.; and Sidney, O. Brief speeches of acceptance were made. Two of these follow.)

Acceptance Address

JOHN P. KOEHLER, M. D., F. A. P. H. A.

Commissioner of Health for the City of Milwaukee, Wis.

IN accepting this health award, for the City of Milwaukee, I do so not only as the head of the Milwaukee Health Department, but also as the representative of the city administration, the local Association of Commerce, the private and public welfare, health, and educational agencies, and many others that have contributed their share toward the health program that has brought this great honor to Milwaukee.

Though ever mindful of our shortcomings, we are proud of the recognition given Milwaukee and thankful to the Milwaukee Association of Commerce for entering our city so successfully in this contest. We are grateful to the Chamber of Commerce of the United States for instituting the Inter-Chamber Health Conservation Contest, not only because it has made it possible for us to have our health work of the present favorably appraised by competent and impartial judges, but even more so because such a contest conducted annually among the cities of this country will stimulate all of us to greater effort in the future.

Many events have occurred in the past that have given a new impetus to health conservation work, but I do not know of any event that has inspired us all with more optimism for the future than the announcement that the business men of our country have enlisted their organizations in disease prevention and health promo-

tion work. I believe that the year 1930 will be the beginning of a new epoch in public health work. It will be the beginning of health work that is based more on sound economic principles than upon spasmodic sentimental efforts.

I do not know of any organization that should be more interested in the conservation of our nation's resources than the National Chamber of Commerce. Our resources do not consist solely of real estate, machines and manufactured products. There is no greater national asset than human capital. According to a well known statistician, our vital or human capital exceeds our material wealth about five to one.

However wasteful we may be with our material wealth and our natural resources, it is not to be compared to our wastefulness of human lives. Sicknes, alone, costs our country \$2,250,000,000 annually. One hundred twenty thousand babies, with a capital value of \$750,000,000, die annually from preventable causes. Every year more than 30,000 young men and women between the ages of 25 and 29 with potential net future earnings of \$750,000,000 die due to their own ignorance and the indifference of the communities in which they live.

It is estimated by those who have given a great deal of study to our annual mortality figures that lives valued at over \$6,000,000,000 can be saved annually through the intelligent expenditure of comparatively small amounts of money. One of our large life insurance companies reports a saving of \$43,000,000 through the expenditure of \$20,000,000 on health education and nursing service among its policy holders. The statistician of this company writes: "There is no greater opportunity for a quick and more certain return on any investment than an investment in public health." It is estimated that if \$2.50 per capita were wisely spent against the preventable diseases and for public health education, our annual death rate could be reduced 20 per cent and our expectancy of life increased from 5 to 7 years.

Public health work is still in its infancy in spite of its marvelous achievements of the past and its great possibilities of the future. There are still many communities that depend upon the crumbs falling from the table of the budget makers for the development of a public health program. They have not yet learned that public health within certain limitations can be purchased with the taxpayers' money. There are still communities that select their health officers according to their political affiliation and qualification.

There are also many communities that prefer to spend millions for the treatment of disease in hospitals, sanatoriums, asylums, and penal institutions rather than to spend thousands for prevention of disease. Dr. Dublin in his book *Health and Wealth* very aptly writes: "A new era of intensive public health work must be brought about, which will make available to the American people the power of this new branch of science. The people of the United States and in fact of the whole world have not waked up to the enormous possibilities of profit in preserving life and health."

I believe that the National Chamber of Commerce has finally started us on this new era of intensive public health work, of which Dr. Dublin writes, and you as members of this great organization are to be congratulated for inaugurating a public health policy which will very likely be the beginning of a public health renaissance. On behalf of Milwaukee, I again beg to express to you, Mr. President, and to the Members of the Chamber of Commerce of the United States my most sincere appreciation for the recognition given our city. I assure you that we shall not rest on our laurels, but shall make a greater effort than ever to make our city, our state, and our country safer and more healthful.

Acceptance Address

FREDERICK C. McLAUGHLIN

Mayor, White Plains, N. Y.

THE people of White Plains express their deep appreciation of the honor which you have conferred upon them by this award.

We come to receive it in no spirit of unseemly pride or truculent boasting, but rather as members of a great fellowcraft, and coworkers in the cause of local self government.

Whatever our city, and the great County of Westchester, of which we are the heart and center, has been able to accomplish in budgeted planning, public works, public health and recreation, and good local government, is, after all, but our modest contribution to better citizenship, and better local government in America. We touch elbows with you in ideals and purpose. If, as Professor Hocking says, the ultimate purpose of the state is the making of men, then the practical accomplishment of that purpose begins with the local unit, in the community where the citizenship of state and nation is in the making, and where the people are united by strong ties of local civic pride and common interests.

Our ideal of local government is that which unites the people in coöperative effort along constructive lines, on the highest common plane, for the common good.

Our creed is that proclaimed by Judge Cooley, in his great book *Treatise on the Constitutional Limitations*, that local self government has been historically, and is today more than ever, the very cornerstone of our free institutions.

The splendid Health Department of the fine City of Syracuse has been richly endowed under the Milbank Foundation. We are similarly fortunate. Our Health Department might well be known as the Dr. Edward G. Ramsdell Foundation. A physician and surgeon of great eminence in his profession, an overseas man, the head of the medical staff of our fine hospital, an over-busy, active man with wide and varied interests, Dr. Ramsdell has for nearly twenty years given freely of his time and great talents to the upbuilding of a model local health unit in our city. That department stands as a monument to him.

What shall we say of such a service? Perhaps George Santayana, in his little classic, *The Sense of Beauty*, has said it for us, when he wrote—"The aesthetic demand for the morally good is, perhaps, the finest flower of human nature."

Not the demand of fear, caution or inhibition, but the spontaneous, pleasurable (and, therefore, aesthetic) demand for the morally good, prompted this service.

When a great physician breaks loose from the selfish allurements of a metropolitan career, to spend and be spent for the common good, with no hope of material reward, we have an example of the finest type of citizenship which local self government and our free institutions can produce. I would gladly travel from White Plains to Washington at any time, to pay my tribute to such a man.

The honor which you confer today upon our city is the hall mark now placed by your great organization upon his splendid gift to White Plains.

We accept the award. We shall hang the trophy in a conspicuous place upon the walls of our Council Chamber as a lasting token and reminder to the people of White Plains of one who stands as an example and as a challenge to the oncoming youth of our city.

I request that Dr. Ramsdell, who is present with me on this platform, receive the trophy in person.

PROGRESS ON FEDERAL HEALTH CORRELATION

WHEN, on April 9, 1930, President Hoover signed H. R. 8807, known as the Parker Bill, this event marked the culmination of more than five years of efforts to bring about some effective coördination of federal health activities. This new law actually does more to improve the internal administration and advance the scope of activities of the U. S. Public Health Service than it achieves in the way of making possible the correlation of our scattered federal health work, but it is, nevertheless, a notable step in the right direction and it represents real progress.

The outstanding features of this law are its provisions for the detail of personnel of the U. S. Public Health Service to other government departments performing health work, when such detail is requested by department heads; the detail of the personnel of the Service to educational and research institutions, and the reciprocal right to offer to qualified scientists the facilities of the Hygienic Laboratory in Washington, D. C.; the establishment of new divisions of chemistry, zoölogy, and pharmacology at the Hygienic Laboratory; the granting of a commissioned status to sanitary engineers, dentists, and other qualified non-medical scientists; an increase in rank and pay for the Surgeon General; and the enlargement of the present Advisory Board of the Hygienic Laboratory to become a national advisory health council. In addition, there are a number of desirable provisions regarding the appointment and promotion of the personnel of the U. S. Public Health Service.

This is essentially the same measure that was adopted by Congress in 1928 but was vetoed by President Coolidge on May 18 of that year. The President gave as his reason for this action the fact that the measure tended to give a military status to officers engaged in scientific pursuits, and took away from the President the right to make certain appointments and thus was unconstitutional. About the only concessions made to this point of view in the present bill were some minor changes in phraseology and the omission of the provision for a much needed Nurse Corps in the Service.

That it should require five years to secure ratification of an important piece of national health legislation is an interesting commentary on government progress in health matters. The agitation for better federal health correlation began late in 1924 at a dinner attended by a group of eminent public health workers, presided over by Dr. Livingston Farrand. Shortly thereafter, a committee went to President Coolidge and urged upon him the desirability and necessity for action in this regard. The President suggested that authentic facts be first gathered. Accordingly, arrangements were made with the Institute for Government Research of Washington, D. C., for a comprehensive survey of federal health work, and the result was a 423-page book,¹ which not only reported and discussed every phase of existing federal health work, but offered a comprehensive and practical plan for co-ordination. Later, an independent study appeared, with still another proposition.²

This scheme of the Institute for Government Research, having the support of the American Public Health Association and other public health, medical, and civic organizations, was presented by a committee to the President on January 14, 1926. Pursuant to his suggestion, a bill embodying many of its salient features was prepared and was introduced in the House of Representatives by Hon. James S. Parker of New York. Due to opposition manifested by the then Director of the Budget, another year elapsed before hearings were held on the bill. By that time opposition had also developed against the first section of the measure, which would have empowered the President to detail by executive order officers and scientific personnel of the U. S. Public Health Service to assist or direct the health work of other bureaus. When the bill was finally reported, this important section, which would have resulted in real coördination, had been deleted.

In this emasculated form, though still carrying other highly significant provisions, the Parker Bill passed both houses of Congress, only to be vetoed by President Coolidge, along with seven other meas-

ures which incurred his disapproval. Congress promptly re-passed three of these bills, but took no action on the equally important Parker Bill. As was poignantly stated³ in our Law and Legislation Section shortly thereafter, "triumph for public health is only postponed, not prevented," and subsequent events have demonstrated that persistence in the promotion of essential national health legislation eventually gets results. Public health has a long heritage in the matter of overcoming obstacles, especially when they are unreasonable.

In the thorough and interesting debate on the current bill in the House of Representatives on March 26, 1930, the statement was made that "the Public Health Service is one of the greatest services of the Government,"⁴ a sentiment which seemed to meet with general approval in that national legislative body. There was also well merited praise for Surgeon General H. S. Cumming and the entire personnel of the Service. In the Senate, where the bill was passed on April 1, 1930, there was, strangely enough, no debate.

It is, of course, gratifying to the American Public Health Association, which passed resolutions in favor of the principles of the Parker Bill at four of its annual conventions, to be able finally to record the success of this measure. The officers, editors, and legislative committee of the Association did valiant work in helping to bring about this result, which cannot help but be fruitful to the great cause of national vitality, to the promotion of which the efforts of all of us are dedicated.

ACCEPTED FOODS

THE Council on Pharmacy and Chemistry of the American Medical Association has announced the establishment of a Committee on Foods. Products which are reviewed and approved by the committee will be admitted to the advertising columns of the publications of the American Medical Association and listed in a *Book of Accepted Foods*.

The *Journal of the American Medical Association* commented editorially:

It is the hope of the committee that its efforts will give stability to a rapidly growing industry and prevent the sinking of the modern food market in a morass of hokum such as engulfed the drug industry in its developing stages.

There is no doubt whatever that a field exists for such an agency. The members of the public health profession will watch the pro-

nouncements of the committee with much interest and will give it their full support.

There is little probability that the American Medical Association will build up around the acceptances of food products the rules and regulations found necessary to protect the public against nostrums and drugs. Presumably all foods have some food value, whether or not they are advertised for health, and it is doubtful whether they would have a deleterious effect upon the health of consumers. This cannot be said of proprietary medicines, some of which are decidedly harmful.

Almost simultaneously with the announcement of the new Food Committee, the press reported that "the use of the word 'health' in connection with foods constitutes a misbranding under the food and drugs act," according to Paul B. Dunbar, Assistant Chief, Food, Drug and Insecticide Administration, U. S. Department of Agriculture. The action of the A. M. A. and the stand of the Food, Drug and Insecticide Administration apparently have no connection, but it is interesting to observe the present trend.

The public health profession has built up the public consciousness to a realization of the value of milk as a food, the benefits derived from a widespread use of orange and tomato juice and of an increased consumption generally of fresh vegetables and fruits. The profession is undoubtedly responsible for the recognition by the public of many food products that now enjoy great popularity. Far-sighted manufacturers and distributors have appreciated for a long time that the right information and attitude of mind on the part of health authorities are essential in assuring the success of any worthy food product.

Health workers through health education and the other means in their power always have drawn a line of distinction between foods of determined value and those whose advertising claims cannot be defended. The Committee on Foods and the Food, Drug and Insecticide Administration will back these previously expressed opinions by official action. It is hoped that the activity of these two groups will result in the further acceptance by the public of those things to which the public health profession has already given its endorsement.

THE HEALTH CONTEST AWARDS

IT is an auspicious day for public health when the leaders of American business pause in their deliberations of major economic problems to recognize and pay tribute to successful health administration. This happened on May 1 in Washington, D. C., at the Annual Meeting of the Chamber of Commerce of the United States, when awards in the first Inter-Chamber Health Conservation Contest were made.

The speech of the president of the National Chamber who personally presented the awards is printed on another page of this issue of the JOURNAL. Two of the brief speeches of acceptance made by representatives of the winning cities are also printed. The remarks of Dr. Koehler, Commissioner of Health of Milwaukee, which was the winner of the award for cities of the first class, are quite generally representative of the attitude of the health officers of cities entered in the contest. The remarks of the Mayor of White Plains, winner among cities of the fourth class, are especially noteworthy. His eulogy of the health officer of White Plains will be appreciated by all health officers who have had to face an often unsympathetic city council.

If the Contest does nothing more than secure for the health officers of the country the enthusiastic interest and support of the local councils it will have served an important purpose. If in addition it can direct to the advancement of public health administration, the organized community enthusiasm which has heretofore been principally expended on industrial development or the attainment of commercial supremacy, then a new era is dawning for the health officer.

ASSOCIATION NEWS

THE FIFTY-NINTH ANNUAL MEETING

FOR the first time in its history the Association will hold its Annual Meeting in Texas. The meeting will be extended to include four days in Mexico City. Twice before the Association has met in Mexico City, once in 1892—the 20th Annual Meeting—when Felix Formento, M.D., of New Orleans was president, and again in 1906—the 34th Annual Meeting—when Franklin C. Robinson, LL.D., of Brunswick, Me., was president.

Were the delegates to take advantage of all the courtesies and privileges offered by the very hospitable Texans, the meeting would last through to the end of the year. The Local Committee has planned many trips both for pleasure and for scientific interest.

There will be trips to various cities in Texas, among which will be Austin, the capital, with its many points of interest—the beautiful state capitol, the French Embassy built in 1841 from hand-sawn lumber to house the Ambassador from the Republic of France to the Republic of Texas, and the old Land Office now occupied by the Daughters of the Republic of Texas and the United Daughters of the Confederacy. It was in 1836 that Texas was declared free and independent of Mexico and became a republic; however, ten years later upon invitation from the United States she voluntarily joined the Union.

Delegates will also visit San Antonio, one of the oldest cities in our country. Here is located the famous Alamo (Mission of San Antonio de Valero) established in 1718, but later reconstructed as the Mission San Jose, in which are some of the original carved statues and

paintings sent to America by the King of Spain, and carried through the wilderness by the early fathers. Many other Texas cities have extended invitations. An unusual feature this year will be a rodeo and barbecue at Fort Worth.

The scientific program is taking form and promises to be very complete. The many problems of the modern health officer will be discussed, such as noise prevention, the effects of the obstruction of sunshine in our big cities, smoke, ventilation, etc. Cancer will have a prominent place on the program.

There will be a special session on preventive medicine from the viewpoint of the practicing physician. The reports of committees are always an important feature since these are the results of careful investigation and research, and in general are far more interesting than the name "report" implies. There will be symposiums on undulant fever, typhoid fever, and metals in foods, and a special session on meningitis, with possibly one on psittacosis.

At the Fort Worth meeting, A. J. Chesley, M.D., the president for this year, will go out of office; the President-elect, Hugh S. Cumming, M.D., will become president; and a new President-elect will be chosen.

The Mexican Department of Public Health is sending a delegation of six representatives who will present papers at various section meetings. Dr. Rafael Silva, Director of Public Health in Mexico, will address the General Session on Monday evening.

Besides very good railroad service, there are many automobile roads for

those who may drive to Fort Worth. The Convention and Publicity Bureau of the Fort Worth Chamber of Commerce distributes a map showing the roads through Texas.

It is hoped that there will be a very large attendance. It would certainly be difficult to find a more enthusiastic host than we shall visit for the 1930 Annual Meeting.

GUY L. KIEFER DIES

Guy L. Kiefer, M.D., Health Commissioner of the State of Michigan since March, 1927, died on May 9 of heart disease. He was a Charter Fellow of the A. P. H. A., elected in 1923; and a member since 1907. He was Health Commissioner of the City of Detroit from 1901 to 1913 and during this time the Herman Kiefer Hospital was

built and named for his father. Later, and until his last appointment, he served as president of the advisory council of the State Department of Health. Dr. Kiefer has served in many positions in connection with the A. M. A., the Michigan State Medical Society, Wayne County Medical Society, Michigan Public Health Association, and the Detroit College of Medicine. He was Vice-Chairman of the Public Health Administration Section of the American Public Health Association in 1924-1925, and has been the Michigan Public Health Association representative on the A. P. H. A. Governing Council since 1927.

ANNUAL MEETING—INFORMATION

FORT WORTH HOTELS

For the convenience of delegates, a number of Fort Worth hotels are listed with their rates. A map of the business section of the city shows the location of some of the hotels, theatres, churches, and other buildings which delegates may desire to reach (page 646).

A blank is printed on page 644 which it is suggested that you use to engage your rooms well in advance of the meeting. All applications for reservations should be made directly to the hotels.

REDUCED RAILROAD RATES

A rate of one and one-half times a one-way fare from starting point to Fort Worth will be granted to those attending the Fifty-ninth Annual Meeting, October 27-30.

Do not purchase a return ticket. When purchasing your one-way full fare ticket to Fort Worth, ask the ticket agent for a reduced fare certificate. This you may have validated by the Executive Secretary at Fort Worth and thereby obtain your return ticket at one-half the usual rate.

The reduction is available to all dele-

gates and members of their families attending the Annual Meeting.

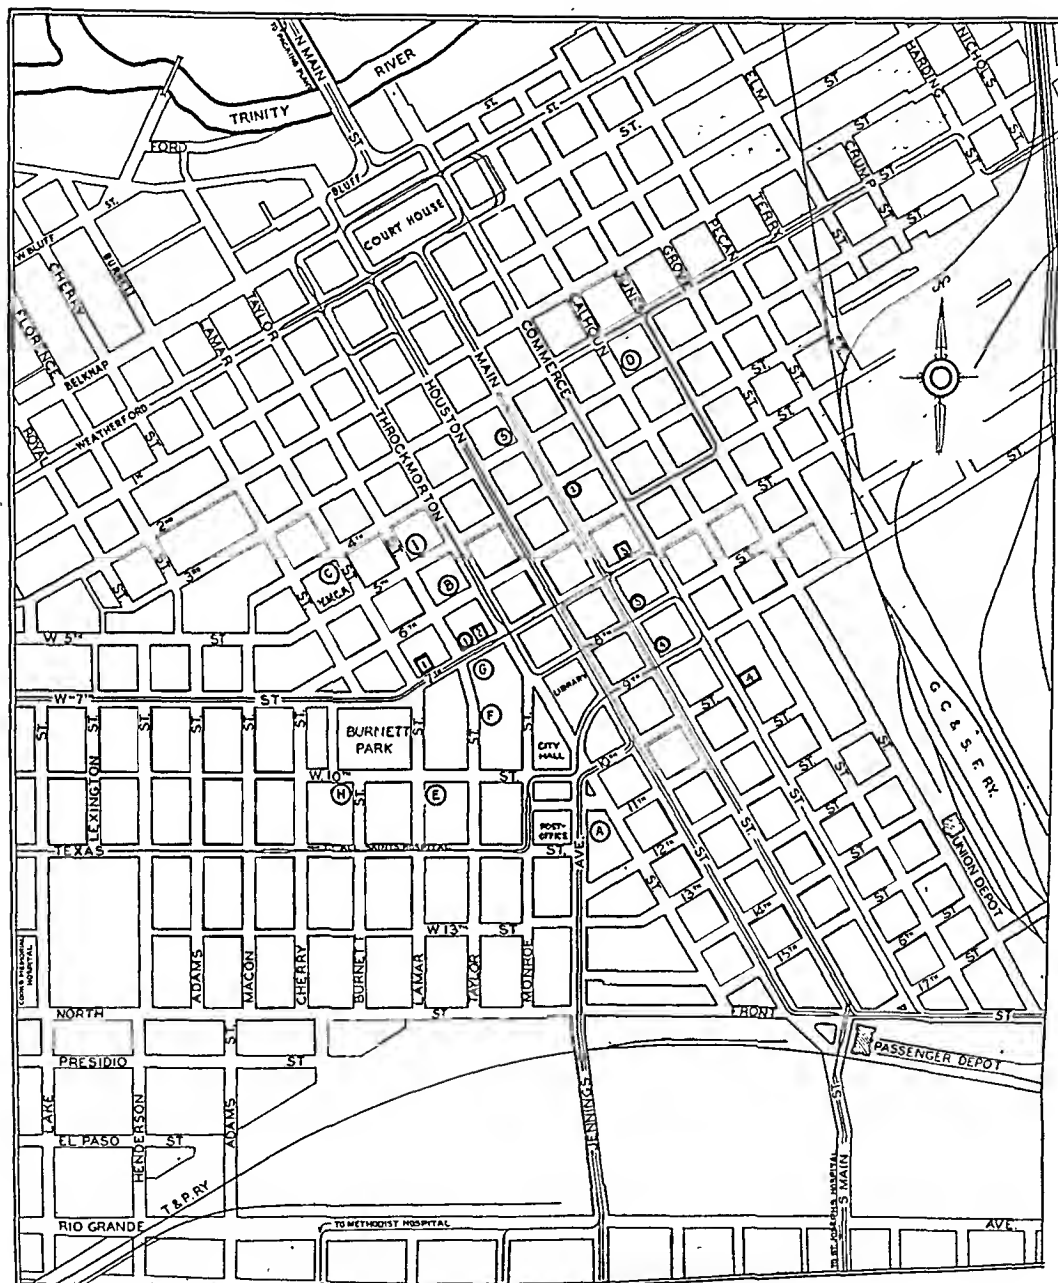

Detailed information regarding transportation will be sent to all members of the Association early in September.

RAILROAD RATES FROM VARIOUS CENTERS
TO FORT WORTH

	Regular Rate One Way	Special Rate Round Trip	Lower Berth	Upper Berth

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Cost of Medical Care—Through its nursing service the Metropolitan Life Insurance Company has obtained figures indicating the amount of money spent for medical care by industrial policy holders. Record has been kept for a period of 6 months for 3,281 families consisting of 17,129 individuals. During the 6 months from January to June, 1929, \$230,907.00 was expended for medical care or an average of \$70.00 per family for the 6-months period or \$140.00 a year. Six per cent of the families reported no expenditure; 40 per cent spent less than \$25.00 each; 80 per cent paid out less than \$100.00 each; 1 per cent expended \$500.00 and over.

The largest share of the money paid out, 43 per cent of the total, went to doctors' fees. Eighty-two per cent of the families had a private physician at one time or another during the 6-months period, while 83 per cent of the families purchased medicines. Hospitals, although used by only 1 family in every 7, accounted for 12.5 per cent of the total amount expended. Families that had the services of a private physician paid him on an average \$37.00 over a period of 6 months. Those that required hospital care paid an average of \$60.00 for this service, and those that had operations paid an average of \$74.00 for this special service.—Lee K. Frankel, *Cost of Medical Care Bulletin* of the Metropolitan Life Insurance Company, 1930.

Tuberculosis in New York City—The tuberculosis death rate in New York City remains high, especially among women from 20 to 25 years and men from 60 to 70. In certain congested sanitary areas the rate still ex-

ceeds 300. During the period from 1898 to 1927 the general tuberculosis death rate declined 70 per cent, from 282 to 86. Since 1921 the rate has remained in the neighborhood of 90 per 100,000 due to many influences, largely economic and racial.—G. J. Drolet, *J. Prev. Med.*, 4: 115 (Mar.), 1930.

Tuberculosis in New Haven—The New Haven Board of Health was created in 1872, at which time tuberculosis was the most important single cause of death. This disease was made reportable in 1905. In 1910 the Health Department started a survey of tuberculosis cases in New Haven which resulted in the establishment of the Municipal Dispensary in 1920 which continued until the latter part of 1926, when the present Bureau of Tuberculosis was organized, thus establishing a unique tuberculosis program.

Of the 1,800 known living cases of tuberculosis in New Haven only 20 per cent have been reported by private physicians, the remainder having been discovered through dispensaries and hospitals. At the present time there are 1,162 available beds for tuberculosis in Connecticut representing approximately 1 bed for each annual death. There is, however, a waiting list in excess of 300.

According to the standard of the *Appraisal Form* of the American Public Health Association, a municipality should have not less than 25,000 hospital days per 100 deaths and 25 per cent of the admissions should be incipient or early cases. New Haven's score on these items in 1929 was 29 out of a possible 35 points, the loss in score being on failure in the second factor of incipient cases. That the city is mak-

ing an unusual effort to hospitalize advanced cases is shown by the fact that while the quota of patient days was 23,750 there were actually given 71,709 patient days.—Herbert R. Edwards' story of Tuberculosis in New Haven *Month. Bull.*, New Haven Health Dept., Mar., 1930.

Refrigerating Systems—Refrigerants used in New York City include ammonia, carbon dioxide, sulphur dioxide, methyl chloride, ethane, propane, isobutane, ethyl chloride, dichloromethane and dichloro-ethylene. Permits are issued by the Fire Commissioner. Refrigerating systems are divided into three classes according to capacity, Class A including those containing not less than 1,000 lb. of refrigerant, Class B including units using from 20 to 1,000 lb., and Class C including those using less than 20 lb.

The use of sulphur dioxide, methyl chloride, ethyl chloride or hydrocarbon refrigerants is not permitted in class A systems. The use of ethyl chloride or hydrocarbon refrigerants is not permitted in Class B systems in built-up sections of the city. About 80 per cent of Class C systems use sulphur dioxide, the remainder using ammonia, methyl chloride or some of the hydrocarbons. Permit is required for Class A and Class B systems but not for Class C. The use of multiple systems is not permitted in tenement houses.—Shirley W. Wynne, M.D., Dr.P.H., and John Oberwager, M.D., *J. A. M. A.*, 94: 1061 (Apr. 5), 1930.

Scarlet Fever in Syria—Measles is 24 times as common as scarlet fever in the Syrian States. Of more than 700 persons tested, of whom approximately half were less than 10 years of age, only 6.5 per cent were Dick positive. It is suggested that the Syrian population has a high resistance to puerperal infection, paralleling its immunity to scarlet

fever. The puerperal morbidity rate was 9.33 per cent in a study of more than 1,000 deliveries in the American Hospital at Beirut, a region of high scarlet fever immunity. The question is raised as to the possibility of this favorable rate being due to a group immunity within the streptococcus group.—Leland W. Parr, Is Immunity to Scarlet Fever a Factor in Puerperal Sepsis?, *J. Prev. Med.*, 4: 105 (Mar.), 1930.

Hookworm in Alabama—The determination of the percentage of the total population which is infested with hookworm does not give a complete and full picture of the problem. Examinations may yield a large number of positive specimens, indicating a high infestation rate, and yet the intensity as determined by ova counts may be low. A survey has been made of the State of Alabama by counties indicating not only the incidence of infection in each county but also the intensity.

The results of this study present an excellent testimonial of the value of full-time local health organization. There are at the present time only 4 counties in Alabama with an intensity index exceeding 20. Three of these counties have no local health department, the fourth one having recently established such an organization. In 1923 in Covington County, when the Health Department was organized, the incidence was 85 per cent and the intensity 56. After 5 years of treatment of cases and improvement of sanitation the intensity index has been reduced to 14, a decrease of 75 per cent.—L. C. Havens and R. Castles, The Evaluation of the Hookworm Problem of Alabama by Counties, *J. Prev. Med.*, 4: 109 (Mar.), 1930.

Philadelphia Hospital and Health Survey—A health inventory of Philadelphia has been taken. A measuring stick has been employed to evaluate the health services performed by both offi-

cial and non-official agencies. Recommendations have been made concerning the state and city governments in so far as they pertain to public health as have also recommendations for the nonofficial health agencies and the general public of this city.

The Department of Public Health is organized under a director of public health, appointed by the mayor, with a board of health consisting of 3 physicians including the director, who is the president. Apparently the Board of Health does not function in a manner common to most boards in other cities and has only about four meetings each year. The department is divided into two main bureaus, one for hospitals and one for health. The staff of the Health Bureau includes 111 physicians and dentists, 95 nurses, 46 other technical and professional personnel, 222 instructors, clerical and other personnel, amounting to a total of 474 employees. This does not include the medical service for public schools.

Judging by the *Appraisal Form*, Philadelphia receives a weighted score of 73.8. The local office for vital statistics is maintained for the most part by the State of Pennsylvania. Vital statistics is given a score of 71 due to failure to print annual reports and to check the accuracy of reported births and deaths and reconcile with reportable cases. Death certificates are not indexed alphabetically and graphic methods are not used.

Communicable disease control receives the high score of 94. It is recommended that there be provided a full-time epidemiologist to be in charge of the Division of Communicable Diseases. Case reports for typhoid fever and diphtheria are below the average. Venereal disease scores only 58 due to incomplete reporting, lack of search for sources of infection, absence of leadership in the division and inadequate field nursing service. Tuberculosis Control

is scored at 76 as cases are incompletely reported and there is inadequate institutional provision for cases.

Maternal Hygiene is given the high rating of 98, Infant Hygiene 88, Pre-school only 52 and School Hygiene 60.

The milk supply comes from 20,000 farms located in 5 different states. About half of the milk is brought to the city by motor trucks. The cream supply comes from 15 states, as far west as Kansas, Mo., Minnesota, and Iowa. The supervision of this milk supply is left largely in the hands of the Philadelphia Interstate Dairy Council. It is not required that milk delivered in the city come from tuberculin tested cattle. There are 34 pasteurization plants for which the official supervision is inadequate. No samples of milk for bacteriological examination are taken before pasteurization, although Pennsylvania has had a law since 1926 requiring the medical examination twice a year of all persons handling food in public eating places. No provision for carrying out the work has been made. Food and Milk Control score 75.

The water supply comes from the polluted Delaware and Schuylkill Rivers and is filtered. In 1927 it was found that one plant failed to meet the U. S. Treasury Department Standards for 2 months, another plant for 3 months, 3 plants for 7 months and 1 plant for 9 months. There are many cross-connections between the polluted river water and the city supply. It is recommended that steps be taken to reduce the pollution of the waters of the two rivers from which the supply is drawn. Sanitation, including water and sewage disposal, scores only 41.

The laboratories located in splendid new quarters score 75, Popular Health Instruction 82, Cancer Control 56, and Heart Disease 91.

It is recommended that there be a separation of the administration of the Bureau of Health from that of the Bu-

reau of Hospitals. It is recommended likewise that the city be divided into 10 districts with approximately 200,000 population each with the object of decentralizing the field work of the department and that these districts be used as a basis of statistical comparisons with respect to the prevalence of disease.

The Bureau of Hospitals is divided into three main divisions, the Philadelphia General Hospital, The Philadelphia Hospital for Contagious Disease and the Philadelphia Hospital for Mental Diseases. Of the total appropriation of \$5,500,000 of the Department of Health for the year 1929, the Hospital Bureau received \$4,600,000 and the Health Bureau only \$820,000. In 1928 Philadelphia spent \$.52 per capita for health services. It is recommended that this be increased to at least \$1.00.

Philadelphia's first hospital, opened in 1751, cared for 68 patients. Today there are 58 hospitals caring for 200,000 bed patients and serving 500,000 in the outpatient departments. Within the city limits there were 10,732 beds available in 1928. By 1930 it is planned to have 12,198 beds in the Philadelphia area which will provide 5.1 beds per 1,000 persons for the Metropolitan District. Two special incidence surveys were made to determine the utilization of the hospital beds.

In 1928 the Philadelphia hospitals were used to 67 per cent of their rated capacity. On the census days 19 per cent of the patients had their homes outside of the city. It is recommended that at least 1,000 more beds be made available in convalescent homes and 1,500 in homes for chronic cases. Negroes constituted 14 per cent of the patients in the hospitals on the census days in comparison with 7 per cent in the general population.

During 1928 there were 89,851 surgical operations performed in the hospitals, 26,838 of them for removal of tonsils and adenoids.

In 1919, 38 per cent of the cases hospitalized were medical, but by 1928 this had dropped to 26 per cent. In 1928, 51 per cent of the total births in the city occurred in hospitals. —Haven Emerson, Sol Pincus and Anna C. Phillips, *Philadelphia Hospital and Health Survey*, 1929, published by the Philadelphia Hospital and Health Survey Committee, 311 S. Juniper Street, Philadelphia, Pa.

The Influence of Non-Resident Deaths upon the General Death Rate in Large Cities—With the assistance of health commissioners in the large cities we were able to prepare a table which reveals to what extent non-resident deaths affected the crude death rate in 1929 in the respective cities. We submit the data for the benefit of officials who love to revel in vital statistics.

The subject is not a new one. For years and years the statistical session of the American Public Health Association has been grappling with the problem of charging these deaths properly. We all know that the non-resident death must be credited to the city or subdivision in which it occurs. This rule was established by the U. S. Bureau of the Census and on the surface it appears to be a good one with the breaks about fifty-fifty; but a glance at the table shows that there is a wide variation in the cities which have been listed in this study.

In New York, Chicago and Detroit the influence of non-resident deaths upon the total number and the crude death rate is slight, and in all likelihood is reconciled by the number of residents of these cities who died in other places. On the other hand, the percentage of non-resident deaths in Boston, Minneapolis and Pittsburgh seems to be unusually large.

Even in the intermediate group we have reason to believe that in some of

the cities the number of non-resident deaths is out of proportion to the number of residents who died elsewhere.

The reasons advanced by health commissioners for the relatively large or small number of non-resident deaths will bear reflection, but for the sake of brevity we shall only express group judgment.

In San Francisco, Buffalo, Cleveland, Washington and Cincinnati the location of hospitals, sanatoriums and institutions within the corporate limits of the cities undoubtedly has a bearing upon the large number of non-resident deaths charged to these cities.

Then again not a few cities, notably Kansas City, Mo., Buffalo, Cincinnati, Washington, D. C., and Pittsburgh, are metropolitan areas, the hospitals of which draw upon neighboring cities and states. Health commissioners believe that this has much to do with the large number of non-resident deaths recorded in their cities. The Government Hospital in Washington and a State Hospital in Minneapolis account for a large number of non-resident deaths.

San Francisco, Boston, Cincinnati and Baltimore are centers of medical teaching and this factor may enter the quotient of non-resident deaths.

Oddly enough in three cities, Minneapolis, Rochester and Milwaukee, a good many resident deaths occur in institutions just outside of the city limits. These tend to neutralize to some degree the non-resident deaths in the respective cities.

Labor importation and a large lake front apparently account for quite a number of non-resident deaths in Cleveland and Buffalo.

Vaughan advances the judgment that the number of hospital beds has much to do with the number of non-resident deaths. Under-hospitalization doubtless keeps out of the city many who would come for hospital treatment. To be

specific: Detroit has available only 5,107 hospital beds, one for each 513 of the population, while in Cincinnati they have 1 bed for every 200 inhabitants. In this respect Cincinnati approximates the accepted standard.

Quoting Bolduan, we agree that

When a non-resident dies of an accident there is no question that this should be properly charged to the city as one of its health hazards. Obviously, the death of a non-resident following surgical interference or medical treatment in hospitals should not be charged up locally. In other instances an individual investigation would often be necessary to determine whether the death should be charged to the city in which it occurs or to the place of residence.

Until we have reciprocal provision by which deaths of non-residents can be allocated to the area in which they have residence or in which the cause of death was contracted, and this will be a gigantic undertaking, we shall have to be contented with the present regulation.—William H. Peters, M.D., Health Commissioner, Cincinnati, O.

NON-RESIDENT DEATHS

LABORATORY

C. C. YOUNG, D. P. H.

MUER'S BACTERIAL COUNTING STAND

FRANK E. HALE, PH. D., F. A. P. H. A.

*Mt. Prospect Laboratory, Department of Water Supply, Gas & Electricity,
New York, N. Y.*

THE counting stand here described has been in use at Mt. Prospect Laboratory for the last ten years. It may be readily made at any laboratory and is here much preferred to the artificially lighted counting arrangements on the market.

The accompanying illustration gives a satisfactory idea of the apparatus. The base is a wooden block $1\frac{1}{2}$ inches thick, 13 inches long in front, 12 inches long on the rear side and 6 inches deep. To this base is fastened a steel rod $\frac{1}{4}$ inch in diameter, 15 inches long, and bent at an angle of 130° at a point 5 inches from the upper end. The rod is threaded at the bottom, is inserted in the rear left hand corner of the base and fastened with a nut underneath.

A piece of tin plate or other thin metal, 14 by 24 inches, is bent to fit the wooden block and fastened securely on it. The upper front edge of the metal on each side is rounded and bent slightly outward. A glass petri-dish cover about 4 inches in diameter is ruled by a scratch diamond into twenty equal sectors. This is inverted and fastened with plaster of Paris in an iron ring about $4\frac{1}{4}$ inches inside diameter, which has a screw clamp attached for fastening to the rod. The entire apparatus, including the plaster of Paris, is now given several coats of a flat black paint. An opaque eye-shade is mounted on the iron ring as shown.

When ready for use, the iron ring with glass dish should be adjusted in

such a manner that no direct light reaches the eyes of the observer but only the black background is in the line of vision, that is, the upper part of the ring should be almost level with the top of the metal back.

The plates are placed in the glass cover and the colonies counted by means of a small hand lens of the usual magnification. For use with daylight a window should be used furnishing well diffused or reflected light and not direct sunlight. For artificial light a 25 watt electric bulb placed 8 inches back of the cabinet at a height of 18 inches gives fairly good results. In no case should the light be arranged so as to strike the eyes of the observer, but it should illuminate the sloping underside of the plate.

THE DDE — A NEW RESEARCH MICROSCOPE FOR THE SCIENTIST

R. W. ABELL

Bausch and Lomb Optical Co., Rochester, N. Y.

A NOTABLE contribution to aid the work of the research scientist is the newly designed DDE Research Microscope, the latest product of the Bausch & Lomb Optical Company, Rochester, N. Y., in laboratory equipment.

FIGURE I—DDE RESEARCH MICROSCOPE

The DDE marks a radical departure from any former type of research and photomicrographic microscope. The outstanding differences in construction from previous types are instantly noted from the illustration.

Most noticeable of these new ideas in design is the inclined position of the binocular eyepiece which allows the user to sit at the instrument in a natural up-

right and comfortable position. This is an especially commendable feature for continual observation over protracted periods.

The stand of the DDE Microscope also represents an innovation in design, the stage being directly in front of the operator. This "turned about" position offers much greater convenience of manipulation of objects on the stage and of the substage parts.

This new research microscope has been developed by the Bausch & Lomb Engineering Bureau from suggestions first offered by Dr. Lester W. Sharp of Cornell University, with later helpful criticisms submitted by Dr. L. F. Randolph of the U. S. Department of Agriculture and Cornell University.

DESIGNED FOR PHOTOMICROGRAPHIC WORK

Since the advent of the binocular body, with its necessary prisms and mechanisms, there has been considerable weight placed upon the delicate fine adjustment mechanism. This weight has been too great to secure the responsive action necessary when working at high magnifications. However, the design of the DDE relieves the adjustment of this extra weight. This will be of special value in photomicrographic work where it is necessary to make long exposures.

The instrument may be equipped with either the regular single objective binocular body tube for visual use and also for drawing with the camera lucida, or with the single tube for photomicrographic work.

For photomicrographic work the mi-

roscope is placed in a horizontal position, resting upon three points of support provided on the two arms and base. This leaves each part intact and the stage vertical.

UNUSUAL FEATURES IN MECHANICAL STAGE AND SUBSTAGE

The mechanical stage has many points which make for unusual facility in research work. It has forward and back adjustment by rack and pinion and transverse adjustment by multiple screw. These adjustments are operated from the right hand side of the stage and the stage may be completely rotated with the objective in focus without interference. The specimen may be firmly fixed in position—a very desirable feature in photomicrographic work.

The substage is of the usual form, but combines many excellent features for fine focusing of condensers, dark ground illuminators, etc. A novel feature of the substage is a supplementary condenser on a swing arm. The focus of this condenser is so selected that the field of a 16 or 32 mm. objective may be entirely filled with light without moving the substage or any of its elements from the usual position for high power objectives. Both high and low powers will function properly without readjustment of the substage condenser.

NEW RESEARCH LAMP DESIGNED

The development of the DDE Microscope made it advisable to design a new type of lamp, one particularly adapted to research microscope work. As a result, the No. 1815 Research Lamp has been produced by B. & L. as a fitting complement to the new DDE Microscope.

FIGURE II—RESEARCH MICROSCOPE LAMP

This new lamp meets two requirements which few designs satisfy: the one of utilizing the full aperture of the microscope condenser (up to N. A. 1.40) and the other of transmitting sufficient light to make possible critical illumination of the specimen under observation. Adjustments and focusing devices are conveniently placed, and the entire lamp is scientifically correct in every detail.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Maternal Mortality in America—A few preliminary tabulations have been made in regard to the maternal mortality study carried out in 13 states, under the direction of the state departments of health with the coöperation of the U. S. Children's Bureau, from January 1, 1927, to December 31, 1928.

A total of 3,234 maternal deaths was reported in the 13 states. The cause of death for nearly 800 of these was albuminuria or convulsions. Prenatal care has been a big factor in reducing maternal deaths from albuminuria and convulsions, and 373 of the women who died from this cause had no prenatal care; only 20 had the best grade of prenatal care, although 76 had care regarded as good.

Of the total 3,234 deaths, 1,278, or 40 per cent, were due to septicemia; and 570 of the deaths from septicemia were preceded by abortions, 309 of which were self induced. Thus, one-fourth of the women who died from sepsis might have lived if interference had not occurred.—Blanche M. Haines, *U. S. Daily*, Apr. 2, 1930.

Poliomyelitis in Maryland—In 1928, out of 287 cases of poliomyelitis reported in Maryland, 126 occurred in Baltimore and 161 in the counties. The epidemic could not be traced to any special focus and could not be regarded as having originated in any one district. Infectiousness of the disease was doubted because of the large number of families in which only 1 case occurred. In 1916 in Baltimore there were 2 cases in the same family in 5 instances; 3 cases in 1 instance; and 7 cases in the same house but in different families in 1 instance. In the 1928 epi-

demic in rural districts there were 2 cases in 3 homes and 3 cases in 1 home.

An analysis of 1,521 cases which have occurred in Maryland showed that 68 per cent were in the age group 0 to 5 years. Of the 287 cases in 1928, 35.54 per cent occurred in age groups 1 to 4 years and 36.24 per cent in the age group 5 to 9 years, while only 3.48 per cent occurred under 1 year. The greatest prevalence of the disease extended over the months from July to November with the peak of the epidemic reached in August when 125 cases were reported, remaining high with 100 cases in September and then showing a gradual decline throughout the remainder of the year.

For 1928, a total of 16 deaths, 13 males and 3 females, occurred in the counties of Maryland, and 11—7 males and 4 females—in the city of Baltimore. Ten deaths occurred in the age group 0—4 years; 7 in the 5 to 9 year group and 4 in the 10 to 14 year group. Of the total deaths 1 was in a child under 1 year of age and 6 were in patients over 15 years of age. The fatality rate for the epidemic of 1928 was 9.0, the lowest rate recorded during the period 1916 to 1928. For the epidemic year 1916, the fatality rate was 31.9, and for the interepidemic year of 1922, the rate was 35.9. The intensive program for early diagnosis, hospitalization, serum treatment and observation of contacts was early inaugurated and was undoubtedly largely responsible for the low fatality rate.

In a study of all cases treated during the 1928 outbreak at Johns Hopkins Hospital, it was found that of 49 patients treated before the onset of paralysis, 92 per cent recovered entirely; of

36 treated shortly after the onset of paralysis, 40 per cent recovered. In a series of 184 untreated cases, all but 14 developed paralysis and 30 per cent recovered. In 54 cases investigated during the 1928 epidemic, the leg was found to be the most frequent single involvement.

The intensive program carried out in Maryland showed that by the use of serum, early hospitalization and the services of an orthopedic surgeon during the whole course of the disease, a low mortality rate, a very low average of total paralysis, a reduction of paralysis of the severe grade and complete prevention of deformities can be expected.—R. H. Riley, *J. A. M. A.*, 94: 550-556 (Feb. 22), 1930.

Poliomyelitis in Ottawa, 1929—There were in all 176 cases reported in the 1929 epidemic of poliomyelitis in Ottawa. The ages of the patients ranged from 7 months to 25 years, averaging 7.43 years, with a maximum incidence between 4 and 5 and between 8 and 9 years. Sixty per cent of all cases reported were males. A noteworthy feature was the comparative rarity of the disease during the first year of life, there being only 3 cases reported.

In all, 181 suspected cases were brought to the hospital for diagnosis or treatment. Fifteen of these cases had lumbar puncture done and received 20 c.c. of serum; they did not have sufficient symptoms to warrant a diagnosis of poliomyelitis and were discharged. Twenty-five other cases that were suspected were later diagnosed as other conditions, 3 cases being pneumonia, 2 pyelitis and 1 each as brain tumor, diphtheria, scarlet fever, acute rheumatic fever, and meningococcus meningitis. All of these received serum at admission when spinal puncture was done. Of the remaining 141 cases that were diagnosed as poliomyelitis, spinal puncture was done in all but 3 cases.

In 18 no cell counts were done but 15 of these were already paralyzed on admission. Convalescent serum was administered to all cases in which paralysis had not been established for more than 2 days. Twenty-five c.c. was the usual dose of serum administered intramuscularly.

Fever was present in 88 per cent of the cases but was rarely over 103°. Headache was the next most common symptom. Rigidity of the neck occurred in 65 per cent of the cases and pain and stiffness of back or limbs in 47 per cent. Tremor and sweating, very common symptoms in other epidemics, were noted in very few cases.

Of the 141 cases treated, 109, or 77.4 per cent, recovered completely and 29, or 20.5 per cent, recovered with paralysis. Of the 31 showing terminal paralysis, 26 already had paralysis on admission, including 2 of the deaths. Of the 115 cases that did not have paralysis on admission, 94.8 per cent recovered completely and 5 recovered with paralysis; one of these cases which developed paralysis had, owing to a temporary shortage of serum, received only 10 c.c. on admission and developed paralysis within 24 hours. One case died without paralysis.—T. A. Lomer and W. T. Shirreff, *Canad. M. A. J.*, 22: 228-234 (Feb.), 1930.

Rheumatic Disease in Children—It was observed that 15 per cent of children over age 3 attending two hospitals in South-East London were treated for rheumatism. A detailed study was made of 250 rheumatic children attending these hospitals. Of these, 180 were out-patients and 70 were watched as out-patients after a prolonged period of treatment in the country. All of the cases were observed for at least 6 months and often for 3 years. Among the 250 cases, 3 girls were affected for every 2 boys and this sex preponderance was more

marked in chorea, the proportion being 1.9 girls to 1 boy. Rheumatism was rarely found before 4 years of age, and chorea a little later, 6 or 7 years. A family history of rheumatism occurred in nearly 60 per cent of the cases but in only about 20 per cent of some non-rheumatic controls. Chorea was found more often where there was a family history of chorea.

In this series, 135 attacks started in the 4 months from November to February, compared with 71 from May to August—a proportion of nearly 2 to 1. Of the 250 cases, there were 41 with related tonsillitis. In 14 cases, rheumatism started at least 5 days after the onset of tonsillitis and in 4 others it started soon after, the interval not being known. Chorea was not observed under age 4 although there were 8 cases of rheumatic pains younger than that.

A systolic murmur was heard during the height of illness in about half of these patients and was much less common in chorea than in other cases of rheumatism. Of 47 cases of persistent mitral murmurs, there were 18 who had signs of mitral stenosis. Two were only 6 years old, 4 were 8 years old, and 8 others were under 14 years. Only 7 had aortic incompetence. Enlargement was found in 37 of the 180 out-patient cases. Permanent signs of heart disease remained in 15 per cent of the out-patients and in 30 per cent of those that had been in-patients.

There was no evidence that tonsils of rheumatic children were more septic than those of non-rheumatic children. Of the 24 children who had tonsillectomy before the onset of the rheumatism, 14 developed chorea and 10 developed rheumatic pains in their first attack, the first manifestation being more commonly chorea than rheumatic pains. This was contrary to what happened in non-tonsillectomized children. Tonsillectomy before there were any

signs of rheumatism (on an average 2 years before) did not prevent its onset or diminish its frequency, nor did it lessen the incidence of rheumatic carditis.—M. Campbell and E. C. Warner, *Lancet*, 1: 61-66 (Jan. 11), 1930.

Public Health in Iraq—The latest report on the administration of Iraq, issued by the Colonial Office, shows that 24 hospitals and 78 dispensaries are maintained. The total number of beds in the hospitals is 1,205. The accommodations in Baghdad and Mosul are unsatisfactory. Serious cases are turned away daily. The government has under consideration a scheme for increasing the beds for free patients at the Royal Hospital, Baghdad, from 250 to 500. A new hospital for Mosul of 220 beds has been included in the building program of the government for 1929.

There were no epidemics of general ailments such as malaria or influenza during 1928. Iraq is unfortunate in having so little assistance from voluntary sources in the field of medical work. There is still difficulty in finding Iraqi doctors to fill posts in out-stations. There is also a shortage of other trained medical personnel, such as pharmacists and nurses.

The number of births registered in Baghdad (with a probable population of 250,000) in 1928 was 5,167; in Basra (80,000) 980; and in Mosul (80,000) 2,763. The deaths registered in 1928 were 6,396 in Baghdad; 1,670 in Basra; and 2,686 in Mosul. In the absence of reliable census figures, it is impossible to calculate birth and death rates with any statistical value for these towns. The percentage of deaths under 1 year was in Baghdad 30.7, in Basra 26.3, and in Mosul 39.9. Maternity and child welfare work is being gradually developed in the large towns.—*Lancet*, 228: 386 (Feb. 15), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Basing Sewage Works Requirements on Stream Pollution Studies—The city of Middletown, N. Y., discharges its sewage, with some tannery and gas works waste, into the Monhagen Brook $5\frac{1}{2}$ miles above its junction with the Wallkill River. As this river is not used for any public water supply, it is only necessary to insure that no nuisance is caused to riparian owners.

As a result of the refusal of the taxpayers to accept plans drawn up for a sewage disposal plant, an investigation of the self-purification accomplished by the brook and the river was undertaken. As a result of examinations made at stations on the brook and on the river above and below the mouth of the brook, it was clearly established that the self-purification of the brook and the dilution of the river afforded completely satisfactory treatment of the sewage and that at no time was any excessive burden being placed on the river.

It was thought, however, that the formation of sludge banks in the brook might cause troublesome additions to the load during dry hot weather, and plans for a disposal plant consisting of sedimentation tank with separate sludge digestion have been accepted.—A. C. Purdy, *Eng. News-Rec.*, 103: 813, 1929. (From Papers of Water Pollution Research Board, England.)

The Sewage Treatment Plant of Königsberg, Prussia—An account is given of the development of Königsberg's sewerage and sewage treatment systems. The growth of the population, the addition of effluents from two sulphite pulp factories and alterations

in the state of the Frischer Haff River were among the causes which necessitated a treatment plant.

The difficulties caused by the difference in the specific gravity between the domestic sewage and the cellulose effluent were met by adding most of the cellulose effluent to the night flow and treating it in the second plant.

The first plant is situated at the end of the first third of the main sewerage canal which is closed to this point. The effluent must leave this plant in a fresh condition but the soil and ground water conditions do not admit of deep tanks, so that the settling tanks are shallow, with channels from which the sludge is pumped daily. A description and plans of this plant are given.

The sewage leaving this plant contains a small quantity of sludge which, after aeration in the sewage canal, assists the deposition of further sludge in the second plant farther down the canal. In connection with this second plant, a description is given of the pumping measures necessary to lower the ground water level and of the building of the concrete settling tanks. The tanks have each two channels from which fresh sludge is removed by two mammoth pumps on a traveling carriage which can be transported from one tank to another. Above the nozzles of the pumps are arranged heavy chains which scrape the sludge from the sides of the channels.

These pumps and the traveling carriages are illustrated and described and an illustrated description is also given of the engine house, which contains two mammoth-dredger plants for removing sludge from the sludge reservoir to the

drying ground, and four double-acting water-cooled compressors for supplying compressed air to pumps and dredgers.

The working costs of the plant as a whole and of its different parts are given.—R. Bruche and G. Sattler, *Gesund. Ing.*, 52: 808 & 827, 1929. (From Papers of Water Pollution Research Board, England.)

An Activated Sludge Plant with Novel Features—A description is given of an activated sludge plant installed at Apeldoorn, Holland, for the treatment of slaughterhouse waste by surface aeration. This plant consists of a bar screen, a grease catcher, an aeration tank, a sedimentation chamber, a practically flat-bottomed septic or digestion tank, a grease pit and a sludge pit.

Wooden racks or paddles turn diagonally to the influent and keep solid matter in suspension. Ordinary rotary, street cleaning brushes, which are totally submerged just below the surface and chain driven from a motor driven line shaft, are used for surface aeration. Owing to the air spaces between the bristles a considerable amount of air is beaten into the sewage, an even flow of which is produced by the brushes.

The effluent from the treatment of the waste, whose strength is considerable, is colorless, odorless and quite clear. The reductions in alkalinity and oxygen consumed, which are shown in the results given, indicate the high degree of purification accomplished. The installation of the plant was inexpensive.—*Water & Water Eng.*, 31: 425, 1929. (From Papers of Water Pollution Research Board, England.)

The Dewatering of Sewage Screenings—This article is largely given over to a description of the methods employed for dewatering, including pressing and centrifuging, at various plants. There are also data as

to the amount, and character, with analyses, of the screenings produced at a number of cities, covering in all about 25 plants in this country and abroad.

Fine screenings from normal city sewage usually amount to 15 to 25 cu. ft. per million gal. of sewage, weigh 50 to 60 lb. per cu. ft. and contain 75 per cent to 90 per cent water and 80 per cent to 90 per cent volatile matter (dry basis). Pressing is described as it is carried on in Washington, D. C., Boston, Baltimore, Dallas, New York, Milwaukee, Dayton, Miami, Rye, N. Y., Long Beach, Calif., and other places. Centrifuging is described as practiced at Reading, Pa., and Cleveland, O.

Conclusions are that dewatering screenings to an extent when they may be burned without difficulty may be accomplished by pressing and probably by centrifuging. With the increasing number of screening plants, and a growing insistence on hygienic conditions, this method seems likely to develop more in the future.—Kenneth Allen, *Pub. Works*, 60, 11: 414 (Nov.), 1929. Abstr. W. A. Hardenbergh.

The Significance of B. Coli in Water—Although a few years ago water was considered safe for domestic use if *B. coli* was absent in 1 c.c., the more recent bacteriological opinion seems to indicate that no water can be considered satisfactory for domestic use unless free from *B. coli* in 50 c.c., or even 100. Since almost no raw surface water is probably consistently free from *B. coli* in at least 10 c.c., this higher standard implies that no surface water is satisfactory without some treatment.

The cities of Glasgow, Manchester, and Dundee, having a total population of over 3,000,000, have been using unfiltered water for more than 50 years, and in the case of Dundee, *B. coli* is seldom absent in 5 c.c. Notwithstanding this, the incidence of disease belonging to the water-borne group during

that period will compare favorably with that for similar diseases in cities using filtered water. As a matter of fact, during the period referred to there has not been a single case of any of these diseases attributable to the water supply. The writer suggests, therefore, that there is too much significance attached to *B. coli* as an indicator of pollution of a pathogenic nature.

The city of Dundee carried out some experiments to show the possibility of *B. coli* pollution from gulls. Results were such that it was not unreasonable to assume that 100 gulls could contaminate a reservoir of 100,000,000 gallons, so that a positive reaction for *B. coli* could be obtained in 40 c.c.

A comparison is made between the standard for water and that laid down by the Scottish Board of Health Milk Order for 1923. In the case of Grade A milk it is required that *B. coli* should not be found in .01 c.c., while in the case of Grade A pasteurized, the limit is 0.1 c.c. When it is considered that milk has a greater scope for and risk of infection from disease producing organisms than water, the writer suggests that it is inconsistent to lay down higher standards for water than for milk, in so far as *B. coli* content is concerned. Further, the inference is drawn that when the water supplies of Glasgow, Manchester, and Dundee are compared with the standards for milk set up, it is impossible to avoid the conclusion that the presence of *B. coli* in 5 or even 1 c.c. does not indicate a condition which is incompatible with safety to health.—George Baxter, *Water & Water Eng.*, 31, 366: 262–264 (June 20), 1929.

Some Troublesome Weeds Found in Water Supplies—The author deals with the algae and their behavior as contaminating agents in a water. A general description is given of the appearance of the blue-green algae, the

green algae, including the desmids, and the diatoms.

The algae secrete oily compounds, the chemical nature of which is not completely understood. These compounds, which are produced during the growth of the organism, are analogous to essential oils and are responsible for the characteristic odors of the species. Other odors are produced when the organisms die and decay.

The algae show variations in their seasonal occurrence. Diatoms appear in the spring, give place to green algae and blue-green algae, and reappear in the autumn. The diatoms generally appear after periods of stagnation and during periods of vertical circulation. Algae growths may be controlled by shutting out the light, by chemical treatment with creosote, hypochlorite or copper sulphate, and by combined filtration and aeration which is the most effective method yet advocated.

The influence of environmental, physical and chemical conditions, the algae themselves, their distribution and behavior, and their effect on water supplies all require further investigation.—P. D. Strausbaugh, *W. Va. Univ. Coll. Eng. Bull.*, 1928, Series 14 (*Proc. 4th Ann. Conf. Water Purification*), 102. (From Papers of Water Pollution Research Board, England.)

A Study of Hookworm Infestation in the Field—This is a report of experiments on certain aspects of the hookworm problem in relation to the use of night soil as fertilizer. Mixtures of urine and feces, spread on the surface of a field or buried to a depth of 1 foot, permitted development of infective larvae, except in winter, when the eggs died. When night soil was stored in water, the eggs died without any development, within 9 weeks in summer, 5 to 6 in winter. The author concluded, therefore, that living hookworms were present on Japanese manured soil, ex-

cept in winter, and except also in rice fields, etc., which were under water.

As substantiation of such conclusion he studied the nematodes isolated from farm soil with Baermann's apparatus, and found hookworm in the soil, easily distinguished from 43 types of free living nemas. Of 50 yards which had received night soil 2 to 3 weeks earlier, 28 were positive for hookworm larvae. As a final test he himself walked in known infested soil in May and July, becoming infected upon each occasion to the accompaniment of many of the classical symptoms, his egg output per day going from negative to 50,000 and after the second infection to 250,000.

In summary "the author would infer that the principal source of hookworm infection in the Japanese rural districts is the barefooted life on farm field, i.e., skin infection—and that infection in water, such as in rice fields, ponds and others, occurs very rarely."—Y. Minamizaki, *J. Pub. Health Assn. Japan*, 5, 7: 1-3 (July), 1929. Abstr. Norman R. Stoll.

Sterilization of Dairy Utensils with Humidified Hot Air—In an effort to determine the value of humidified hot air for sterilizing dairy utensils, its operation was compared with that of two other types of known efficiency, namely, the steam boiler and the steam electric methods. A galvanized iron tank, connected with a steam boiler and fitted with a sump in which immersion type electric heaters or electric air heaters could be placed, was used for all three methods. The time and temperature relationships inside the tank, the power and energy requirements, bactericidal efficiency, moisture remaining on apparatus and utensils after sterilization, and the practicability of operation were measured in a series of tests of each of the three methods.

A temperature of 210° F. was reached in 54 minutes with the humidified hot

air method, using a 9.58 kw. heater; in 51 min. with the steam electric method, using a 16.24 kw. steam electric type heater; and in 76.5 min. with the steam boiler, including the time necessary to generate 80 lb. of steam. There were slight variations in temperature with the humidified hot air, while the sterilizer was heating up. This method was the most economical in cost of energy for operation, and the steam electric method was the most expensive. The humidified hot air method left the utensils practically dry, while an appreciable amount of water was left on them when steam was used. The bacterial reduction was quite satisfactory with the hot air method. In practice this method proved a satisfactory and efficient means of sterilizing dairy utensils. The chief disadvantage of the method is that it furnishes no hot water for washing utensils.—A. W. Farall and W. M. Regan, *Calif. Sta. Bull.*, 468: 13, 1929.—Experiment Station Record, 61, 5: 467-468 (Oct.), 1929.

The Bottled Mineral Waters. Investigations on Their pH and Their Content of Coli Bacilli and Other Bacteria—The pH was determined in 21 (apparently French) bottled mineral waters. The values found ranged between 6.0 and 7.6, but different samples of the same brand gave very close checks. Little difference existed between the pH of bottled and fresh mineral water. The number of bacteria per c.c. was between 0 and 10 in 10 cases, between 10 and 100 in 5 cases, between 100 and 1,000 in 3 cases and 400,000 in 1 case. Several waters contained a large number of molds. Only 1 brand contained coli bacilli (200-500 per c.c.).—Jean Bance and Louis Caillon, *Arch. Inst. Pasteur Tunis*, 18: 199-201, 1929.

Town Penalized for Failure to Chlorinate—In the spring of 1927,

Kingsville, Ontario, a town of about 2,400 population, suffered an epidemic of typhoid fever, there being about 50 cases, of which 10 or more proved fatal.

A recent court decision awarded \$2,000 damages in a suit against the town brought by a relative of one of the deceased. The text of the decision is given and the conditions leading up to the epidemic are described. Sewage-disposal and water supply had been a problem for many years.

There is no sanitary sewer system and inhabitants have been permitted to connect septic tanks and cesspools with the storm sewers, which ultimately discharge into Lake Erie, the source of the water supply.

Since 1917 the Ontario Department of Health has endeavored to compel the municipal authorities to improve the sanitary conditions and chlorinate the water supply. Pressure filters were

installed in 1921, and in 1926 it was decided to construct a new intake. The old intake, however, failed in February, 1927, before the new one was completed. An opening was made in the settling basin and a trench dug connecting the basin with the lake, the water so obtained being passed through the plant into the distribution system.

A notice was published in a local paper advising boiling of all water used for drinking purposes. The ice disappeared from the lake prior to March 24 and the first case of typhoid developed on April 1. Systematic chlorination was adopted on and after April 14. New intake was completed shortly after and the storm outfall sewer discharge is now being chlorinated.—Anon., *Contract Record and Engineering Review*, 43, 38: 1114–1116 & 1118 (Sept. 18), 1929. Abstr. Rudolph E. Thompson.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

On the Diagnosis and Treatment of Lead Poisoning—Some new facts are presented under this title. The diagnosis of lead poisoning rests on a proper evaluation of the following matters: (1) Exposure to lead compounds, (2) susceptibility to lead, (3) symptomatology, (4) physical findings, and (5) laboratory findings specifically related to lead to a greater or lesser degree.

Any type of lead dust, regardless of its solubility or particulate size, is capable of producing lead poisoning if present in sufficient concentration in the air inhaled by animals or man. It has been established, on a fairly sound basis, that the regular inhalation through the usual working day of air containing less than 5 mg. of lead per 10 cu. m. of air does not produce serious lead intoxication in individuals of a representative group (Legge and Goadby). Hence a lower figure than this should be maintained where lead compounds are used. Repeated examinations of the air breathed by workers should be made.

Examination of the feces and urine of representative groups shows the following: (1) 36 children, 71 medical students, and 84 workmen without known exposure to lead nevertheless showed lead in the feces ranging from 0.074 to 0.087 mg. per gm. of ash, and in the urine 0.080 to 0.096 respectively; (2) 114 of the same type of workmen but with a history of previous exposure showed 0.100 in the feces and 0.130 in the urine, respectively; (3) 70 garage workers showed 0.130 and 0.120 respectively; (4) 108 moderately exposed workmen showed 0.192 and 0.181 re-

spectively; and (5) 122 severely exposed workmen showed 0.730 and 0.210 respectively. Thus the degree of exposure may be measured by a study of the excretions.

It is clear that the exposure to lead on the part of most non-industrialized patients is small, but the conditions of life on earth do permit such exposure. That such small absorption produces a regular excretion of lead militates against our ancient concept of an almost quantitative accumulation of lead in the tissues and equally strongly against the notion that lead may exist in an immobile state in the body. It demonstrates also that the toxicity of lead has a quantitative aspect. Lead excretion increases with increased exposure. In the individual case in which the diagnosis is at stake the examination of a single sample of feces or urine or both does not yield adequate information. This is especially true if the exposure has been discontinued for some days or weeks prior to examination.

A table is given showing the excretion of lead in the feces and urine of "J. F." following removal from exposure, when the immediate drop in the amounts present is most significant (explained as that cleared from the bodily passage ways which had been inhaled during the last work day), and the marked effect is noted of administering Epsom salts, calcium lactate, and even work in temporarily increasing lead excretion. As excretion continues, the amount of lead in the body diminishes, and the rate of excretion drops.

Analysis of the blood for lead of 5 persons in whom there was little or no exposure and who showed no symptoms

exhibited a trace of lead in 3 instances. A similar analysis of the blood of 9 persons who had a moderate to heavy exposure to lead but showed no symptoms exhibited lead in measurable amounts in 5 instances, a trace in 3 instances, and none in 1 with only moderate exposure. Thus, it would appear that, even under conditions of severe exposure, measurable quantities of lead in the circulating blood are inconstantly found. A single subject may show lead in his blood at certain times and not at others, while one with a large lead content (in his tissues) is likely to show a higher lead content in his blood.

The usual method of examining blood smears for stippling is somewhat easier than any other method of obtaining information regarding lead exposure and absorption, and its sensitivity for the purpose for which it is used is entirely satisfactory. A table is given showing the close relationship of stippling with the degree of exposure in representative groups of persons. Unfortunately stippling occurs in other afflictions than lead poisoning and even exposure to sunlight involves some changes in the blood cells.

The foregoing evidences of exposure to lead, and those of absorption, may not be used as a means of recognizing the presence or the likelihood of lead intoxication. "All that can be established by the study of lead excretion, lead content of the blood, and histological variations on the blood is the extent of the individual's exposure," but these evidences arm the industrial physician with information needed to limit further exposure of men.

When does lead absorption develop into lead intoxication? What are the earliest evidences of intoxication? In the author's experience there occurs usually first a progressive rise in the number of stipple cells, followed by a drop in the red cell count and in the hemoglobin content. These occur very frequently without any subjective symp-

toms, or any other physical signs. Hence, these progressive changes may be regarded as suggestive of impending intoxication while the diminution of the hemoglobin content is to be regarded as an actual evidence of intoxication, with or without associated subjective symptoms (excepting those instances in which the blood changes are due to other causes).

In regard to susceptibility and without attempting explanations, there are certain influencing conditions of which the most important are: (1) general vascular disease, (2) general hepatic disease, (3) tuberculosis, (4) active chronic infections in general, (5) starvation, and (6) fatigue. In addition, immaturity in both animals and man is an important factor. Hence there must be care in the exclusion from lead occupations of persons in whom any of these factors are at work. "In connection with vascular disease I cannot but state my tentative conclusion that lead intoxication is only doubtfully to be regarded as a cause of vascular disease." It rather appears that arteriosclerosis among lead workers is little higher than in a corresponding age group of the general population, but the occurrence of lead intoxication in persons with arteriosclerosis is high indeed.

That the symptoms of lead poisoning are due to lead in the circulating blood has been stated by many persons, but up to the present there has been no direct evidence that such is the case. In fact, previous attempts to discover lead in the blood have failed because of a lack of adequate methods. The author finds (by the methods which he has used) that in all cases of acute illness studied to the present in connection with lead poisoning, lead is uniformly found in the blood in measurable quantities. "It may well be that a range of concentration may be found constantly associated with the presence of symptoms." At present it may only

be said that finding more than traces of lead in the blood indicates the strong probability of significant recent exposure.

Encephalopathy is the most dangerous form of lead intoxication and the most unsatisfactory to treat. Furthermore lead palsy, while usually not serious as to life, presents a gloomy prognosis as to the return of normal function. "Nervous tissue has a striking ability of fixing such lead as reaches it." (Tables show the retention of lead in the brain of rabbits after long periods of time, even 17 months.) If one has absorbed lead in the brain he may presumably develop encephalopathy at any time afterward. The distribution of lead in the tissues of a typical fatal case in one "J. G." is shown in a table from which "the index of selective absorption" by different tissues showed in descending order (percentages) the following: rib bone 31.71, long bone 19.51, cartilage 11.22, bone marrow 6.75, spleen 2.10, liver 1.73, pancreas 0.88, brain 0.85, kidneys 0.53, heart 0.33, blood 0.32, lung (rt.) 0.26, lung (lt.) 0.13, and nil in fat, spinal fluid, and suprarenal. The case in question died with a terminal lobar pneumonia and, in fact, there is quite commonly a contributing factor in the development of lead encephalopathy, which the author has seen follow a prolonged anesthesia and evidently also influenza. In such the differential diagnosis is a matter of some doubt. Conditions which produce cerebral anoxemia are strongly suggestive factors in developing acute brain symptoms due to lead.

In regard to treatment, early lead intoxication recovers spontaneously, when exposure to lead stops, unless other ailments are present, or there has been a repeated or prolonged injury from exposure over a considerable period of time. Recovery has especially to do with the elimination of lead from the body and the patient left alone will tend

to eliminate from his body the offending agent.

... In time he will excrete all of the lead except that portion which is firmly bound in his tissues. At present, there is no evidence that lead is fixed in any tissue of the body, with the exception of the central nervous system. Therefore there is no need for the use of therapeutic measures which will aid in the elimination of lead from the tissues except in the case of the brain. Here, unfortunately, no such measures are known, though it is likely that experimentation will discover them.

The usual measures for increasing lead elimination during the period of intoxication are dangerous and unnecessary except what may be accomplished by increased use of water. Decrease of the symptoms of lead poisoning is due partly to the large amount absorbed from the blood into the tissues and partly to that eliminated.

Experiments with rabbits show that the normal distribution of lead is (percentages) as follows: bone 6.55, central nervous system 4.13, liver 1.09, skin and hair 0.93, blood 0.82, etc. In one rabbit injected with 12 mg. of lead the total found in the tissues was 5.91 and that in the excretions 5.16, thus accounting for a recovery of 11.07. The speed with which lead is removed from the blood—this being done almost quantitatively when lead is absorbed by way of the alimentary tract—saves the other tissues from the effects of high concentration over long periods of time. It is doubtful if symptoms occur so long as lead is distributed in the normal fashion (above referred to). In regard to the time relations one table shows that the lead is out of the blood after 16 hours and appears to have reached its "normal distribution" after 65 hours.

Two further tables show the effects of treatment, the general principles for which are summarized thus: (1) remove from exposure; (2) put at rest (rest favors distribution of lead in the tissues, while exercise promotes excretion); (3) give a cathartic, as Epsom salts; (4)

give water in large quantities and at the same time (5) "A sufficient amount of calcium, potassium, and sodium salts to maintain a proper salt balance in the tissues"; (6) large quantities of citrus fruit juices; (7) a full mixed diet to maintain normal physiological processes; and (8) strictly avoid agents which are believed or known to promote a quick release of lead from the tissues.

In the case of cerebral involvement, empirical procedures will have to be followed but encouraging results have been obtained from intravenous injections of hypertonic salt solutions. Coexisting chronic diseases must be treated and especial attention given to an infected mouth, chronic infections in general, caution against fatigue, the use of alcohol, and the avoidance of exposure to acute infections, cold, and inclement weather.

With the above attention, the typical case of lead poisoning, without involvement of the central nervous system, will recover uneventfully, and in most instances will show little or no residual effects from his experience.—

Miners' Nystagmus and Incapacity for Work: A Clinical Study Based on an Analysis of 512 Cases—These cases, which were examined during the period 1921-1929, were drawn from various sources in the South Wales coal field. Among the conclusions are the following:

1. Defective eyesight does not render an underground worker more likely to develop nystagmus than a man with good sight.

2. Defective vision has no influence on the average period of incapacity nor the period of recovery from the first attack of nystagmus.

3. The average case of miners' nystagmus, if observed over a period of about 9 years of incapacity, may be expected to work underground for about 3 years, and to be totally incapacitated for about 2 years.

4. There is a definite risk of recurrence

of incapacity on the average in 3 to 4 years after resuming work underground.

5. The average period of recovery from the second attack is a little longer than from the first attack.

6. The average age at which disease appeared was much the same in neurasthenic cases as in other cases, viz., 41 years, and the average period spent in underground work before incapacity was about 27 years.

7. Young men are less incapacitated than elderly men, but there is no evidence that elderly men are more prone to a recurrence.

8. There is no evidence that a man with only one eye is likely to develop the disease at an early age.

9. There is some evidence that the average period of recovery from the first attack is a little longer in highly myopic men than in those with normal vision.

10. Illness or injury may determine the onset of miners' nystagmus.

11. Miners' nystagmus is distinctly different than other forms of nystagmus.

12. The oscillations of the eyes may be worse in one eye than the other, and this sometimes has a relation to visual acuity.

13. The wearing of corrective lenses does not influence recovery from the disease.

Proposed Standard Smoke Ordinance—A joint committee made up of representatives of the American Society of Heating and Ventilating Engineers, the Stoker Manufacturers' Association, the American Civic Association, and the Fuel Division of the American Society of Mechanical Engineers, has prepared a tentative draft of a standard smoke abatement ordinance composed of 11 principal sections and ready for adoption by any city.—U. S. Bureau of Mines, *Information Circular 6262*, Mar., 1930, 6 pp.

Typewriting and Lead Poisoning—The author investigated a well known make of typewriter which has been on the market since 1903 and has discovered that the keys make a contact with a lead cushion which prior to that date was composed of felt. He studied the effects of using the typewriter in the

Caisse Regionale d'Assurances et du Service de Sante in Leningrad in a bureau using from 5 to 9 of the machines, and elsewhere. He discovered lead in the air in the vicinity of the machines to the extent of 0.19 mg. per cu. m. of air, an amount which is 3 to 4 times that contained in the air about a linotype machine (0.05 mg.).

Selecting 21 typists at the end of the day, he had them wash their hands in a weak solution of acetic acid and obtained on the average from each one from 0.33 to 0.586 mg. of lead. This quantity considerably exceeds that found upon the hands of the workers in the printing establishment who were operating presses (0.292 mg.). In respect to symptoms he found the typists had gastrointestinal troubles to the extent of 55 per cent, including constipation and abdominal pains, accompanied sometimes with colic. In comparison he found that girls working in a carton box factory had similar complaints only to the extent of 19 per cent.

Blood examinations of the typists showed considerably more of anemia than among the carton box makers, the

hemoglobin ranging as low as 66.7 in the former as against 72.7 in the latter. Furthermore, 77 per cent of the typists had a hemoglobin of 70 or below as against only 22 per cent in the carton box workers. He therefore concludes that their symptoms are closely associated with lead intoxication.

In regard to prophylaxis, the author recommends the replacement of the lead cushions with cork covered with velour.—Lipkovich, *Vestnik Sovrennoi Meditziny*, Moscou, juillet 1929. (Office International D'Hygiene Publique, *Month. Bull.*, XXII, 1: 161-167 (Jan.), 1930.

"The Healthy Worker"—This pocket size bulletin of 48 pages, interestingly illustrated, is prepared in simple, effective language for distribution directly to workmen. Principal factors concerning the care of the body and common abnormal conditions compose the 23 separate articles. A health maxim is boxed in at the end of the various articles.—C. O. Sappington, National Safety Council, 20 North Wacker Drive, Chicago, Ill.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Long Time Feeding Experiments with Activated Ergosterol—I—Reviewing previous work of other investigators, it is pointed out that irradiated ergosterol fed in quantities up to 10,000 times the minimum antirachitic dose is not fatal to rats. Quantities from 50,000 to 100,000 times overdosage are rapidly fatal. In nearly every case the previous works failed to determine the potency of the product they employed and experiments were carried out for short periods covering at the most only a few months of life in the rat. In the studies now reported the experiments were conducted from infancy to old age.

The activated ergosterol used in these experiments was prepared by exposing the solution in arachis oil to the rays of a mercury vapor quartz lamp. It was found that there was no great difference in the toxicity of ergosterol irradiated in the oil, in ether under a reflux, or as crystals in the air, provided the antirachitic potency of the preparations was sustained. It is pointed out that it is meaningless to state, as is often done in the medical literature, that a certain number of milligrams of activated ergosterol were administered. The potency of irradiated ergosterol varies enormously with the conditions under which activation is performed, values from zero to a million times the potency of average cod liver oil being obtainable.

Rats receiving 100 times overdosage of irradiated ergosterol for 10 months showed growth at normal rate. They reproduced normally throughout the second generation. In experiments in which much larger doses were administered it was shown that the effects of overdosage with activated ergosterol be-
